1. The cicatrising element is the same in intestinal cancer as in epithelial cancer everywhere else. Starting from the centre of disease the contracting influence spreads out along the strands of fibrous tissue in all directions, pulling towards the tumour-centre all the tissues entangled in the fibrous meshes. The tissues, so drawn in and compressed, atrophy. In pure cicatrising cancer—"atrophic scirrhus" as it is called—invading the breast this is best shown. The fatty lobes all round the growth are dragged in and atrophy from the pressure, while the encircling strands of fibrous tissue increase in size and strength. Close to the tumour, all around it, there is an area of deeply pigmented fat, the cells being compressed or destroyed and the pigment with a little liquid only remaining. As the contraction goes on lobe after lobe is encircled and pulled in; the cells are destroyed and all that remains is a small globular cyst containing dark-brown liquid fat. The contracting influence is not confined to fat but invades muscle. Indrawing and atrophy of muscle is best seen in cancer of the tongue and at the angles of the mouth, but may be found where atrophic scirrhus is invading pectoral or intercostal muscles. It is always a marked feature in intestinal cancer and ultimately results in its complete disappearance. Here, however, the process is obscured by the indrawing of muscle hypertrophied from physiological over-action. [All these points were demonstrated in specimens passed round amongst the audience.] In the intestines this process of cicatrisation of fibrous tissue and its effects are well displayed.

First, there is indrawing of fatty tissue from the neighbourhood all round the bowel. Where the growth starts on the mesenteric aspect the piling up of fatty tissue may be so marked as almost to suggest the presence of a fatty tumour. If there is not much fat to be drawn in the appendices epiploicæ are huddled up together around the growth. In one case of cancer in the transverse colon nearly the whole of the omentum was drawn in. In every case this aggregation of fatty tissue round the growth-centre is found and sometimes to an extraordinary extent.

Secondly, there is constriction of the gut from indrawing of the submucous and subserous fibrous tissue. The musculature being in the grasp of the fibrous tissue outside and inside it and being contractile is pulled inwards and remains as an atrophied fibrous ring. It appears thickened and later, in certain circumstances, does become greatly thickened, but this thickening is apparent rather than real and arises from the fact that muscle forming a ring with a diameter of perhaps a quarter of an inch is thicker than the same muscle stretched out to form a ring with a diameter of two inches or more. One striking result of this constriction is that the mucosa, being mobile, is puckered up into vertical folds inside the contracted lumen everywhere except just over the growth, where it is hypertrophied and often diseased and always adherent. The compressed and folded mucosa soon breaks up and exposes the muscular coat.

Thirdly, there is shortening of the gut. This is, of course, to be expected from the universal distribution of the fibrous tissue affected. The bowel gathered in from above and from below towards the cicatrising centre is folded on itself, producing great ridges towards the mucous surface, between which lie pouches. These ridges and pouches are most marked on the proximal side of the growth, because coincidently with the contracting influence of the fibrous tissue there is going on dilatation of the whole tube as an effect of the obstruction to the passage of fæces.

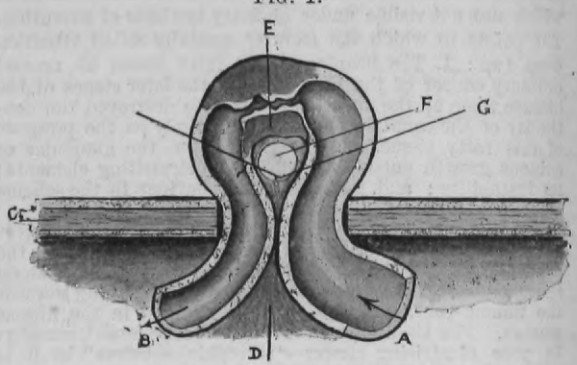
2. The occurrence and the behaviour of the true acinous or glandular growth are the same in cancer of the intestines as in cancer of the breast or other tissue. It is nearly always secondary. It practically never appears in the centre of the scirrhoid or cicatricial tissue, but always at the periphery. It would seem as if in the centre of the grip of the contracting fibres no cell proliferation were possible; it occurs only outside it or at its free margin. Section after section of cancerous growths show this with a uniformity which is almost absolute. In the intestine this growth, of course, begins in the mucosa. In the grip of the stricture it breaks down almost at once and exposes the muscular coat. Above and below the stricture it grows readily enough and may attain to dimensions sufficient to be classed as a tumour. This is the well-known lip of growth which is found at one stage of all intestinal cancers on each side of the structure. Meanwhile the growth pierces the exposed musculature and burrows amongst the subperitoneal tissue, begetting secondary developments of acinous cancer. But these growths also soon break down towards the surface and the access of pyogenic organisms leads to suppuration and phagocytosis and the formation of granulations. As the new growth and the encircling fibrous and muscular tissues break down the calibre of the bowel enlarges, so that in an advanced case it may actually be greater than normal. Meanwhile, as destruction is going on inside fatty tissue is being drawn in from the tissues around and the intestinal walls are pulled from above and below close up to the tumour area. The condition then would be: at the centre of the disease a ring of fatty and fibrous tissue covered with granulations; above and below this and joined to it the divided and folded extremities of the bowel; and above and below all a lip of hypertrophic glandular growth. [All these points were demonstrated on specimens and illustrated by drawings.]

I say nothing about the histological structure of the growth. That it is cylindrical epithelioma is in keeping with the behaviour of epithelial cancer everywhere—namely, that it follows the tradition of the structure it originates in. All that I insist upon is that associated with the cancerous growth in the intestine proper there is always an indrawing and cicatrising of fibrous tissue at some period of the tumour-growth and that but for this action, which draws in fresh tissue to the cancerous area, perforation would in most cases take place earlier and more frequently than it does.

Clinically cancer of the bowel first signalises its presence as a stricture causing intestinal obstruction. This condition is often known as "ring cancer," a very suitable name. If it happens that obstruction is not produced its presence is not proved till some months later when it will have grown into a tumour and is discovered by palpation through the parietes. This tumour is hollow, and is composed of a conglomerated mass of cancerous, fatty, and inflammatory tissue holding together the more or less completely destroyed ends of the bowel. Obstruction is not associated with it, but cachexia and wasting nearly always are. It might therefore be regarded as fortunate for the patient when attention is early called to the presence of intestinal cancer by its producing obstruction, for then the growth can be completely removed. Later, with the presence of a tumour there is probably invasion of neighbouring tissues and systemic infection, and operation, even if primarily successful, is not likely to be radical.

Cancer originating in some structure outside the intestine and invading the bowel secondarily from its peritoneal surface is often mistaken for true intestinal cancer. It may

Digitized by Google



cause obstruction by pressure or by actual ingrowth, but the most common way in which it causes obstruction is by kinking of knuckles of intestine which become adherent to it.

In the treatment of intestinal cancer four surgical measures are available. 1. Removal of the growth—enterectomy or colectomy,—this being, of course, limited to suitable cases. 2. Formation of an artificial anus above the growth—colotomy, or "colostomy" as it is more properly named—may be done either to avoid death from obstruction or to prolong life and make it more comfortable. 3. Intestinal anastomosis—short-circuiting or the joining of healthy intestine above the tumour with healthy intestine below so as to exclude the tumour-growth. This operation should, I think, be limited to cases where there is obstruction and where the tumour is unremovable. It is, of course, unsuitable for cases of cancer in the rectum or low down in the sigmoid. It is useless if there is a large tumour, for obstruction rarely arises in these cases and perforation is equally rare, while the risks of perforation are practically the same whether cancerous fluids or fæces are extravasated. 4. Enterostomy, or the insertion of a small tube into the bowel in certain inoperable cases chiefly of peritoneal cancer associated with great distension from gas, is a measure of undoubted benefit. It is not intended to permit discharges of fæces, but simply to provide an exit for the great quantities of gas which are excreted in such cases and which cause much pain and general disturbance. In connexion with each of these operations I desire to make some critical suggestions which are the outcome of personal study and experience.

1. *Enterectomy.*—Ring cancer is, as already stated, usually discovered during operation for intestinal obstruction. Now, enterectomy for cancerous growth as part of the operation for obstruction is a very grave—according to some authorities an unjustifiable—operation. As usually performed, at one sitting, I admit that the operation is almost unjustifiable. Carried out in the way I recommend, in two stages, I have had 5 enterectomies all successful, and of 2 performed in other ways, 1 was successful and 1 fatal. In all these it is to be noted that the call to operate was from the obstruction and not from the new growth. Tumour-cancer, which is rarely associated with obstruction and is usually diagnosed by palpation through the parietes, may be removed by any of the numerous methods of enterectomy at the will of the surgeon, when and how he chooses. Now, the death-rate after operative removal of intestinal cancer in the absence of obstruction is over 25 per cent. of published cases; over all cases it is doubtless well over 40 per cent. This is a terrible mortality, higher, I hope and believe, than it need be. If with the methods in use this is the best that the best surgeons can do, then I am convinced that there is something wrong in the methods. Our methods of to-day are essentially the same as those in vogue a hundred years ago. Have we got into a wrong groove and been following it up too far? Is it not time to break new ground and to make new paths? The best results by the best surgeons—with bobbin, reel, button, plate or simple suture, whether applied end-to-end, or side-to-side or end-to-side—are all bad, terribly bad, and it is not easy to see how on these lines they can be improved. I am going to venture to suggest an abandonment of the old methods and to recommend an operation which I will now describe. I first performed it for ring cancer during obstruction six years ago, and I have performed it for the same disease during obstruction in four other cases. It is, I believe, certainly the best method of dealing with cancerous bowel during obstruction. For tumour-cancer I had meanwhile been doing my share of operations by the ordinary methods, with bone-bobbins, Murphy buttons, and suturing, and had had the ordinary share of success, no better and no worse than my neighbours. But my success has been less for operation without obstruction than for operation with obstruction; *a fortiori*, therefore, I have argued that the operation I adopted of necessity was better than the one I followed from choice. I have now come to the decision to adopt this method for all cases of enterectomy until something better is discovered. I stumbled on the method when operating on a lady patient of Mr. Eadon of Hambrook, who was desperately ill with intestinal obstruction. The obstruction was comparatively sudden in onset; vomiting had existed for a week and an operation was performed in ignorance of the exact cause. A cancerous stricture was found in the sigmoid flexure. This was brought outside; a wooden penholder was passed through its mesentery, after the method of Maydl, and permitted to rest on the parietes, and the intestine above was opened and drained. A week later the growth was cut away and an artificial anus was left over the pubes. This I closed by means of Abbe's catgut rings which I soon had to remove by another operation on account of a new intestinal obstruction which they caused. Then I had other cases, one after another doing well, and each in method showing some improvement on the one before. The trouble was the artificial anus which was left and how to close it without risk to the patient. Finally, I think I have got a method of doing this and now I venture to put before you the whole operation. It is, I admit, not so simple as other methods, but what of that if it gives more safety to the patient? This was the surprising and delightful element of the operation. After the acute trouble from the obstruction was over—a period lasting rarely more than twenty-four hours—there never was a moment's anxiety as to recovery. It was not so much the recovery as the manner of it which impressed one. The patient, so to speak, had the race well in hand and could have carried pounds more in the handicap and won; and therefore until I hear of something likely to surpass it I mean to practise this operation for the future.

The following are the steps of the operation. It is

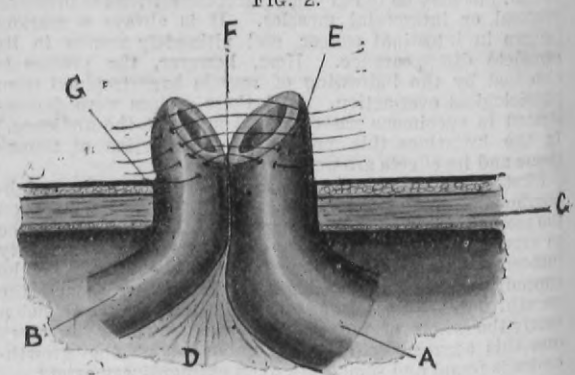


FIG. 1.

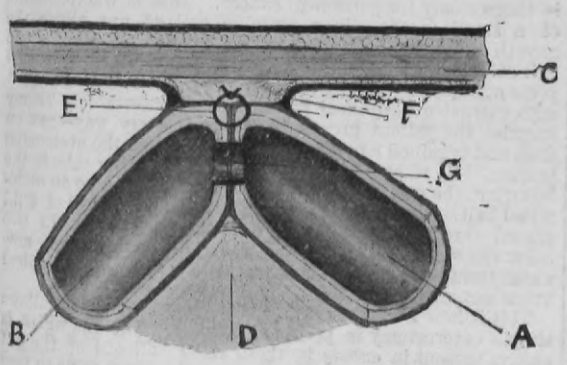
First stage of enterectomy; tumour delivered and fixed. A, Entering bowel. B, Returning bowel. C, Abdominal wall. D, Mesentery. E, Line passing through tumour and stricture. F, Skewer passing through mesentery and resting on parietes. G, Lines of excision.

performed in two stages, the first step resulting in fixation of the diseased bowel outside the abdomen in the parietal incision (Fig. 1), the second in resection of the growth and the necessary amount of bowel and in the suturing of the divided ends and returning them inside the parietal incision but not into the general abdominal cavity. (Fig. 2.)

FIG. 2.



Second stage in enterectomy; tumour excised; suture of bowel begun. A, Entering bowel. B, Returning bowel. C, Abdominal wall. D, Mesentery. E, Lembert's sutures inserted. F, Adhesions between apposed bowels. G, Adhesions between bowel and parietes.

The delivery of the growth is usually quite easy; but sometimes the mesentery is much shortened and then, to get a sufficiency of bowel outside, it may be necessary

Digitized by Google

to divide the mesentery at its deep attachment. If what I have said as to invasion of mesentery by growth be true, then we ought to remove more of the mesentery than we usually do. Not a wedge-shaped piece but a fan-shaped piece should be removed, the handle of the fan being at the centre of intestinal disease. The mesentery should be divided between ligatures suitably placed by transfixion and all suspicious portions should be removed outside. Then through the mesentery and under the bowel should be placed one or more skewers or supporting rods. The skewer or skewers should pass through healthy mesentery because everything down to the skewer is to be removed. The incision may be made anywhere, over the disease always if possible. Sutures of any sort, either in the parietes themselves or between parietes and bowel, are quite unnecessary unless the incision has been made too long, and the gut should be placed on the raw parietal incision. If there is no obstruction the bowel, covered with silk protective or gutta-percha tissue, is left in the wound for 48 hours while adhesions are formed. These are always firm enough at the end of this time. If there is intestinal obstruction with distension, drainage of the bowel above the obstruction must be carried out This is done simply by making an incision in the bowel and inserting a rubber tube on the stretch into the opening and fixing the bowel to the tube by a purse-string suture or any similar simple device. At the end of a week more or less, according to circumstances, the bowel is resected down to the skewers and sutured on the spot by Lembert's method, or perhaps better by Halsted's. This is done outside the abdomen and as it causes no pain an anæsthetic is not necessary. But the bowel has to be returned inside the parietal incision; this requires an anæsthetic, for it means separation of the bowel from the parietes and also peeling of the parietal peritoneum from the muscle. This is a delicate process and one which I have not found it easy to describe, while I cannot say that it is easy to do. The secret is not to disturb the adhesion of the parietal peritoneum to the bowel while it is being separated from the muscle sufficiently to permit the knuckle of gut to be pushed inside. The sutured gut is freed from everything save its parietal peritoneum and is pushed inside with the peritoneum adherent. Then over it the parietes are pulled together and sutured in the ordinary way (Fig. 3).

FIG. 3.

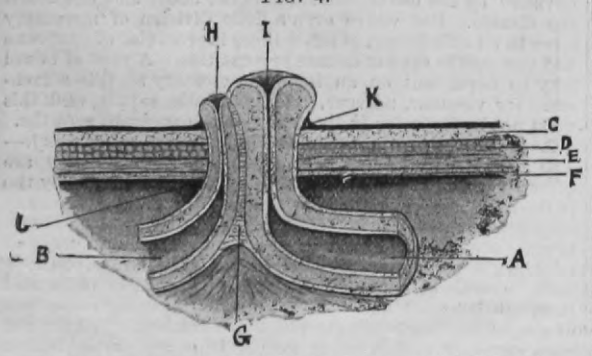
Second stage in enterectomy concluded; suture completed; bowel returned. A, Entering bowel. B, Returning bowel. C, Abdominal wall. D, Mesentery. E, Suture placed in intestinal wall. F, Peritoneum adherent to bowel. G, Opening left at junction of divided ends of bowel.

This is the ideal method; but, as a matter of fact, enterorrhaphy, or the closure of the intestinal opening, may well be delayed for a month or longer. All the time the patient is gaining strength, the swollen bowel is being restored to its natural dimensions, and suturing is really easier. By the insertion of a piece of rubber tubing—the excellent suggestion of Mitchell Banks—the spur is removed and the gut is straightened, so that at the end of this time quite a small portion of the circumference requires suture. An anæsthetic is necessary for the operation because the incision above and below the anus must be extended and the areolar tissue uniting parietal peritoneum to muscle must be freely opened up. The operation is, in fact, the one for closure of an artificial anus which I have elsewhere described and figured and which is done shortly as follows. First, an incision is made through the parietes for a couple of inches above the anus. This goes down to the subperitoneal areolar tissue. The forefinger is inserted into this and is made to separate it freely from the parietes all round the adherent gut. The adhesions to the gut must be divided; they are usually very firm. Then the two ends of the gut with its adherent peritoneum are delivered through the wound and sutured carefully. Finally, it is returned and the parietes are sutured over it.

For the operation primary success can almost certainly be predicted. The charm of the proceeding is that there is practically no danger with it and no shock. If it fails there is no harm done and a very simple subsequent proceeding remedies the fault. A failure here is not death, only discomfort for a few days more. And there are few patients or surgeons who mind this if the risk is thereby greatly diminished. Such is the operation which I venture to recommend for the removal of intestinal cancer. There are, however, certain special conditions associated with removeable cancer of the bowel which may negative this operation. One of these is where the new growth forms the apex of an intussusception—not a very uncommon circumstance.

An operation which I have successfully performed in a case where the growth was not cancerous (already published) would probably suffice for cancerous cases. The operation was done rapidly on the spur of the moment in the case of an infirmary patient gravely ill from obstruction; but on thinking it over critically since I am inclined to recommend it as the best I could have done. When it was found that the intussusception could not be reduced and when it was clear that a tumour at the apex of the intussusception was the cause a vertical incision was made over the growth in the receiving bowel and the growth was delivered through this incision and excised. Transfixion sutures were placed through the divided ends of the bowel. When it appeared certain that the intussusception could now be reduced the vertical incision in the bowel was closed, cleansed, and returned into the abdomen, with the receiving bowel as it was peeled off the intussusception. The divided ends when they were drawn out were joined with a Murphy button, which was the quickest method available where speed was everything. The patient recovered, but not so easily as I could have wished, and I should like to believe that some less dangerous method were available. Mayo Robson has had a similar success with his bone bobbin in a case of epithelioma with intussusception. The operation also would not be a good one where the mesentery was extensively implicated, for extensive division of the mesentery involves gangrene of the bowel. Now, bowel which may become gangrenous is best removed at once. There is certainly a tendency for the muscularly powerful gut above the growth to draw it inside the abdomen, rocking it over the skewer. This can be obviated by the use of two skewers one above and one below the disease. But where even a little division of mesentery close to its attachment is made there is great risk of gangrene and the double skewer cannot prevent this. A yard of bowel may be dependent on an inch of mesentery at this attachment for vascular, nervous, and lymphatic supply, and this must not be forgotten in the resection of cancerous growths.

2. *Colostomy (as done now usually by abdominal section).*—The results of the ordinary operation of colostomy are often such that it is abhorred both by the surgeon and by the patient. Some of its frequent concomitants are certainly unpleasant. It leaks continually; fluid fæces and mucus are nearly always escaping from the anus and trickling over the skin. The intestine prolapses, often a little, sometimes a great deal, and anti-prolapse plugs and pads are invented and worn. Then the opening sometimes contracts and anti-stenosis plugs are inserted. Again the opening gapes and inflating rubber bags are pushed in and blown up. The ordinary colostomy is too often one continuous struggle against adverse influences, and not always a successful struggle. In the ideal colostomy there should be no leakage, no prolapse, no stenosis, and no gaping, and the opening should remain of one size, neither dilating nor contracting. Also, although this is a smaller matter, the anus should rise above the surface so that ejected fæces may be caught in a receptacle and not trickle over the skin. It need scarcely be added that all the fæces should be passed through the artificial opening and that none should pass into the lower bowel. This ideal result may, I think, be confidently expected if the operation is performed on the lines I now follow. It can always be got in the transverse colon; nearly always in the sigmoid colon; and in the majority of



Digitized by Google

cases in the descending and the ascending colon. The difficulties lie in excessive thickness from obesity of the abdominal wall or in great shortness of the mesentery preventing complete delivery of the bowel. I have found these difficulties present to the extent of being insuperable only twice in the last 20 operations I have performed in this way, and then simple modifications brought a fair measure of success.

In forming an artificial anus we ought to study the natural methods of effecting closure of the hollow viscera and follow them. To prevent leakage nature provides a canal lined by mucous membrane and surrounded by muscle. The best examples are the natural anus and the female urethra. A mere fistula, lined by granulations, however long, will always leak, even if surrounded by muscle. We know this too well in renal or biliary or intestinal fistulæ which dribble continuously till permanent closure takes place. The mucous lining then is one essential. Further, it should be surrounded by intact muscle. By the ordinary methods the muscle is divided and sutured closely to the bowel. This is all very well for a week or two, but divided muscle first retracts and then atrophies. Nothing can prevent this; there is no getting over it. Muscular fibres when divided atrophy away from the point of division and become fibrous for some distance away from it. Hence grip is impossible. This results in gaping of the opening. But there is contraction also; the ring of cicatricial tissue contracts if it is not continually dilated by prolapsing bowel, and thus we have as an artificial anus a mere hole in the abdominal wall surrounded by a ring of fibrous tissues and atrophied muscle. Finally, to make matters still worse, instability is given to the whole affair by bringing up the parietal peritoneum to the skin and suturing it there and to the bowel. In the operation which I am about to describe I seek to avoid all these drawbacks and now practically always succeed in doing so.

First, a complete mucous tube is provided, the whole calibre of the gut for at least a couple of inches being used. Secondly, it is surrounded by double crossing bands of intact muscular tissue; no muscular fibre is divided, the bowel is surrounded by what is practically a ring of muscle. Thirdly, the bowel is laid on the raw muscle over its whole thickness and is immoveably fixed there by the strongest adhesions. Lastly, there is no fibrous ring scar to either gape or contract. The following in detail are the steps of the method. The parietal incision, two or three inches in length, wherever made must enter the cavity without the division of any muscular fibre—the fibres are separated by the finger, not cut by the knife. If the ascending or descending colon is to be opened and the incision is made in either loin the skin incision is made along the course of the external oblique, the

FIG. 4.

Cœlio-colostomy; bowel carried through separated fibres of parietal muscles. A, Entering bowel. B, Returning bowel atrophied. C, Subcutaneous fatty layer of abdominal wall. D, External oblique muscle. E, Internal oblique muscle. F, Transversalis muscle, fascia, fat, and peritoneum. G, Intestinal adhesions and mesentery. H, Opening into lower bowel. I, Artificial anus: opening. J, Junction of parietal and intestinal peritoneum. K, Muco-cutaneous junction.

fibres of which are separated; then almost at right angles to these the fibres of the internal oblique are also separated, and the transversalis fibres being unimportant are obliquely divided. For the transverse colon the fibres of the rectus are separated after vertical division of the skin. Then a loop of bowel is pulled through the separated muscular bundles and fixed by a skewer passed under it through the mesentery and resting on the parietal skin, as already described for enterectomy. This is the whole operation. Sutures are superfluous; the muscle closely grips the gut, and if the incision is of the proper size, neither too large nor too small, the apposition is exact. The bowel cannot be drawn inwards; it is held over the skewer more firmly than by any stitches, nor can there be protrusion if the skewer is fixed and a graduated and firm dressing is placed around and held in position by strapping carried round the body. Now I nearly always open the bowel at the time of operation and put in a rubber tube; this permits exit of fluid fæces and gas. At the end of a week the bowel is divided transversely down to the skewer, or nearly so, and the operation is complete. In about a fortnight the bowel settles down to a permanent state, such as is shown in the diagram (Fig. 4). The bowel is firmly gripped by intact muscular fibres. It protrudes a little beyond the skin level and so serves to hold up a rubber ring to which is attached a rubber bag to catch the escaping fæces. The patient has by moving the body some power of relaxing and contracting the opening. Stenosis is impossible, as is dilatation. However firmly the muscle grips there is always this patent mucous canal, for mucous surfaces never adhere and dilatation is impossible, for entire and active muscle never wastes.

A colostomy done in the way I recommend is really little more trouble than a natural anus. It acts for about ten minutes or a quarter of an hour in the morning, the parts are cleaned, a little cotton-wool is placed in the bag, and the apparatus is fitted on, and the probability is that it requires no more attention during the day.

3. *Intestinal anastomosis.*—Of intestinal anastomosis, or short-circuiting, I shall say very little. It is employed, as you know, to cause union between healthy bowel above and healthy bowel below in unremoveable cancerous growth causing obstruction. In the disease we are considering it has, in my opinion, a very limited applicability. But in suitable cases it is an extremely valuable operation, far better than colostomy. As to the method to be followed I prefer the employment of immediate sutures to any mediate methods by plate or button or bobbin. All such openings tend to contract and there is no bobbin possible to be inserted which is large enough to give the requisite size of opening. I have described the methods elsewhere and shall not trouble you with them now.

4. *Enterostomy.*—The only other operation to be described is enterostomy for peritoneal cancer. This is the formation of a small opening in a suitable coil of gut above the growth and leaving in it a rubber tube which permits the exit of gas and fluid. This operation I performed first some years ago hoping thereby to make the latter end of a patient with extensive peritoneal cancer more comfortable. To my surprise the patient greatly improved in every way—put on flesh and regained a passage for fæces through the obstructed portion. He wore a tightly fitting small rubber tube in the intestine, the end of which lay in a bottle fitted to an abdominal belt. Great quantities of gas and a good deal of fluid passed through the tube; the fæces passed on. In two other cases similar results followed. A fourth patient now under treatment has so much improved that both her medical attendant and herself think the tube may be removed.

This is how I try to explain the improvement which follows simple enterostomy in peritoneal cancer. The gas which is always present in excess in these cases balloons up the gut and prevents it from contracting on the fæces so as to pass them on. The gut is powerless to propel; it simply compresses. When the gas is permitted to escape the gut grips the fæces and pushes them on with success. Whatever be the explanation I have little doubt as to the fact that provision for the external escape of gas in certain cases of peritoneal cancer, and perhaps other cases as well, is a surgical measure of real therapeutic value. The operation is so simple that it is scarcely worth describing. All that I would insist upon is that the rubber tube, about the size of a No. 4 English catheter, should be encircled by a tube of the intestinal mucosa and that this in turn should lie between intact bundles of muscular tissue.

WATER-SUPPLY OF CAMBORNE.—At the meeting of the Camborne District Council held on July 1st a letter was read from the Camborne Water Company stating that several improvements had been made by the company since the recent epidemic of typhoid fever.

A CASE OF ACROMEGALY.[1]

BY J. BREWARD NEAL, M.R.C.P. EDIN.,
MEDICAL SUPERINTENDENT, WANDSWORTH AND CLAPHAM INFIRMARY, S.W.;
AND
E. JACKSON SMYTH, M.D., B.S., B.SC. LOND.,
LATE ASSISTANT MEDICAL OFFICER, WANDSWORTH INFIRMARY.

With a Pathological Note

BY S. G. SHATTOCK, F.R.C.S. ENG.,
JOINT LECTURER ON PATHOLOGY, ETC., ST. THOMAS'S HOSPITAL; PATHOLOGICAL CURATOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE patient was a married woman, aged thirty-seven years, of temperate habits, and was admitted to the Wandsworth Infirmary on Oct. 21st, 1893. The following history was obtained from her husband. She had had two children and had previously suffered from chorea, hæmorrhoids, and vomiting of blood. Her present illness was stated to have commenced about fifteen years ago with an attack of hæmorrhage, probably from the stomach. Shortly afterwards her friends noticed her hands to be getting larger and she began to suffer from failing vision, some deformity of her chest also being observed at the same time. During the succeeding seven years her hands and feet increased in size so that she required a larger size in boots and gloves than formerly. At the end of this time she began to suffer from weakness and loss of flesh and a few years later her features were noticed to be undergoing change, the lips becoming larger, the nose more prominent, the eyes protruding, and the whole face becoming lengthened. She became gradually weaker and about a year before admission lost the power in her legs and was obliged to take to her bed. She suffered from incontinence of urine and fæces and occasionally complained of headache. Her appetite was excessive but her general health was becoming worse. Menstruation had ceased shortly after the onset of her illness.

On admission her condition was as follows. She was quite helpless, emaciated, and anæmic, the skin being soft and flabby, the subcutaneous fat almost absent, and the muscles wasted. The nails of the fingers showed a brownish discolouration with longitudinal striation. There was some hypertrophy of the hands and feet, and the bones of the face, especially of the lower jaw and nose, were markedly enlarged. The chin, lips, nose, and forehead were strikingly large, the lower lip when in a passive state hanging down and protruding in front of the upper, giving the patient a fatuous appearance. These points are shown in Fig. 1, which is from a photograph taken soon after admission, and which exhibits a very marked alteration of features when compared with a photograph of the patient fifteen or twenty years previously. The tongue also was considerably enlarged; there were marked proptosis, discolouration of the eyelids, external strabismus, nystagmus, and inequality of the pupils. Vision was completely lost and there was white atrophy of both optic discs. The reflexes were abolished but there was little or no loss of common sensation. There was also general muscular weakness. She exhibited some mental deficiency and her speech was slow and indistinct. She seldom spoke unless addressed, lying for the most part in a quiet apathetic state, and there was incontinence of urine and fæces. The body temperature was subnormal and the pulse was 66 and of small volume. The chest and spine were deformed, the sternum being pushed forward in its upper part, and a condition of kyphosis, most marked in the upper dorsal region of the column, was present. The heart sounds were distant and indistinct at the apex. The thyroid gland was not noticed to be enlarged. The clitoris was greatly hypertrophied. The urine was of low specific gravity but otherwise normal.

The patient was treated with thyroid extract soon after her admission, but after some weeks it was discontinued on account of diarrhœa and vomiting supervening. It was tried on several subsequent occasions for varying periods, but was stopped finally on account of recurrence of the same symptoms. No marked change in her condition was noted as a result of the treatment beyond some improvement in her mental condition up to a certain point. She improved also considerably in her general nutrition, being able during the last two years or so of her life to get up and sit in a chair during part of the day. Measurements taken about nine months before death showed that since admission the hands and feet had diminished slightly in size, while the facial measurements showed an increase over those noted on her admission. As regards her other signs and symptoms she showed little or no change, and except for obstinate constipation there was no particular indication for active treatment. She continued in the same sleepy mental condition, though answering questions rationally when addressed. She suffered from occasional headache but had a good appetite and was able to take a nourishing and free diet. The termination of the case was somewhat sudden, the patient being seized with an attack of diarrhœa and vomiting, which was followed by a rise of temperature, rapid pulse and respiration, with signs of commencing pneumonia. She became rapidly exhausted and died about two days after the commencement of acute symptoms, on June 21st, 1897.

FIG. 1

From a photograph of the patient in 1894.

Necropsy.—The post-mortem examination was performed two days later, when rigor mortis had passed off. The body appeared to be fairly nourished, though there was general muscular wasting and a flabby condition of the subcutaneous tissues everywhere. The enlargement of bones appeared most marked in the head and face, especially affecting the malar prominences and lower jaw; there was general hypertrophy of the features also, as described above, especially of the nose, ears, and lips. The angle formed by the manubrium with the body of the sternum was very prominent, causing a general projection of the front of the chest and some flattening on either side. There was also marked kyphotic curvature of the spine as mentioned above. The hands were flabby and spade-like, but did not appear to be notably enlarged, and on removing one of the metacarpal bones this appearance was confirmed,

[1] The notes of the case were read at a meeting of the Pathological Society of London on Nov. 2nd, 1897.

Digitized by Google

as there was no evident hypertrophy of the bone. The knee-joints were enlarged and thickened, being fixed in a position of slight flexion, the bones being apparently affected by outgrowths of an osteo-arthritic nature. Both feet appeared to be unduly large, prominent, and flattened on the plantar aspect and there was great enlargement of the metacarpo-phalangeal joints of both great toes. The subcutaneous fat was everywhere fairly abundant, especially in the scalp, and the muscles in all parts were pale and flabby. The vertex of the skull presented some irregular prominences in several situations, especially in the right posterior parietal region, the bone in this area being uneven and perforated by small apertures. There was also considerable thickening in the frontal and occipital regions, the sawn surface measuring three-quarters of an inch in places. The cerebral membranes appeared to be normal. On removal of the brain a large tumour was found on the under surface occupying the central portion of the middle fossa of the base of the skull, completely filling the pituitary fossa and extending on each side of this to some extent (see Fig. 2). It was smooth on the surface and

FIG. 2.

View of the base of the skull showing enlarged pituitary body *in situ*.

covered with what appeared to be a prolongation from the pia mater, except on the right side over a small area where this had been torn away. The tumour was roughly divided into two lobes, right and left, the former being slightly the larger, and it measured 3 in. transversely by 2½ in. in the antero-posterior direction. The optic tracts were stretched over the tumour and were much flattened. The pituitary fossa of the sphenoid was enlarged and the anterior clinoid processes were widely separated. The brain itself weighed 44½ oz. and showed a marked concavity on the under surface corresponding to the position of the tumour, and the parts forming the floor of the third and adjoining portions of the lateral ventricles were greatly thinned. Except for this condition there was no other noticeable appearance and the substance of the brain seemed normal. The spinal cord was removed for part of its extent only; no abnormal appearances were seen by the naked eye except a few small bony and calcareous spicules on the inner surface of the dura mater. The thyroid gland was considerably enlarged, weighing 6½ oz. The right lobe was slightly larger than the left, but otherwise the increase in size was uniform. The thymus gland was not seen. The lungs were congested at their bases and posterior parts and there was some early pneumonic consolidation of both lower lobes. The heart was enlarged, weighing 18½ oz. The mitral valve was thickened and showed calcareous deposits and there were old vegetations present on one of the cusps. The tricuspid valve was also somewhat thickened. The liver weighed 72 oz., but beyond general enlargement nothing abnormal was noticed. The spleen was also enlarged, weighing 18 oz. The kidneys were of normal size and no morbid changes were observed on section. The stomach appeared to be healthy except for some congestion of the mucous membrane. The intestines contained an accumulation of fæces in the lower part, but no other abnormal conditions were noticed.

Report by Mr. SHATTOCK. — The thyroid gland was uniformly enlarged but to no very notable degree. To the unaided eye the cut surface presented the structure of an ordinary parenchymatous goitre and the microscopic characters corresponded; the gland spaces, which were of abnormal size, were lined with a single layer of cubical epithelium and enclosed homogeneous colloid. There was no trace of parietal infolding into the spaces as in the thyroid enlargement associated with Graves's disease. Sections of the pituitary body revealed a remarkably uniform structure of polyhedral cells somewhat large in size and without visible intervening substance. There was scarcely a trace of connective tissue stroma, the cells closely filling the meshes of a capillary network and resting directly on the capillary wall. In general characters the cells resembled those of the anterior lobe of the pituitary body. The changes may therefore be classed under the head of hypertrophy, as the enlarged body was everywhere encapsuled and the surrounding bone uninvolved. The metacarpal and metatarsal bones examined showed no enlargement.

THE TREATMENT OF TUBERCULOSIS BY TUBERCULIN R.

BY NATHAN RAW, M.D. DURH., F.R.C.S. EDIN.,
MEDICAL SUPERINTENDENT, MILL-ROAD INFIRMARY, LIVERPOOL;
AND
JOHN HILL ABRAM, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY; ASSISTANT LECTURER ON PATHOLOGY, UNIVERSITY COLLEGE, LIVERPOOL.

IN the *Deutsche Medicinische Wochenschrift*, No. 14, 1897, Professor Koch brought forward his latest work on tuberculin preparations. He makes therein a number of interesting and important observations and the following portion of our paper in inverted commas is a brief summary of his paper.

"Immunity may be either poison immunity or organism immunity and the ideal immunity will include both. Man apparently shows no immunity to tubercle, yet in miliary tuberculosis in man and experimental tuberculosis in guinea-pigs there is a stage in which the bacilli become scanty and difficult to find: here we have an organism immunity which is as a rule too late to be of service." "The one feature in common of the two conditions is a rich quantity of bacilli." "Based upon this glycerine extract of tubercle bacilli was used in treatment and Koch claims that experience has shown that the fear of the dissemination of tubercle bacilli is unfounded, and this agrees with his own experience in men (1000 cases)." "From the therapeutic point of view the glycerin extract gives poison immunity but not organism immunity." "The new preparation, tuberculin R., is obtained by pounding up young virulent cultures of tubercle bacilli in a mortar, treating with distilled water, and centrifugalising. The deposit is dried, again powdered, distilled water added, and again centrifugalised, and the process repeated until the culture is converted into a series of clear fluids. The first fluid obtained differs markedly from the remainder and is rejected; the remaining fluids constitute the new preparation, tuberculin R." "Koch states that tuberculin R. produces marked organism

TABLE OF A SERIES OF CASES OF TUBERCULOSIS TREATED BY TUBERCULIN R.

Case.	Sex and age.	General and local condition.	Treatment.	Condition after treatment terminated.	Weight.	Later history.	Remarks.
1	F., aged 30.	Nutrition poor; anæmia. Temperature normal; weight 98 lb. Sputum copious; tubercle bacilli present. Consolidation left apex.	April 20th, 1897: $\frac{1}{100}$ mg. Dec. 23rd, 1897: 20 mg.	Sputum scanty; no bacilli. Physical signs disappeared.	+ 12 lb.	Feb. 18th, 1898: in good health.	After 2·6 mg. temperature was 101·4° F. After 4·5 mg. temperature was 100·2°.
2	M., aged 37.	Very anæmic; nutrition fair. Temperature, highest, 99° F.; weight 130 lb. Sputum copious. Tubercle bacilli abundant. Consolidation of right apex; some softening.	Feb. 8th, 1898: $\frac{1}{100}$ mg. T.R. April 2nd, 1898: 5 mg. T.R.	Temperature normal; cough and sweats still present. Physical signs unchanged.	- 2 lb.	June 30th, 1898: *in statu quo*; says he feels better.	Treatment stopped as general reaction occurred without increase of dose.
3	M., aged 37. Marked heredity.	Well-nourished; temperature 99° F.; weight 135 lb. Sputum scanty; fair number of tubercle bacilli. Left apex consolidation; occasional "clicking."	Feb. 1st, 1898: $\frac{1}{100}$ mg. May 8th, 1898: 10 mg.	Temperature normal: no cough. Physical signs entirely cleared up.	+ 17 lb.	June 30th, 1898: working and in good health.	After 3 mg. temperature was 102°; marked excitement; after 4 mg., ditto.
4	M., aged 21. Marked heredity.	Fair nutrition; temperature 100° F.; weight 122 lb. Sputum copious; many tubercle bacilli. Consolidation of left apex; softening; no cavity; some dissemination.	Feb. 1st, 1895: $\frac{1}{100}$ mg. May 9th, 1898: 6 mg.	No improvement.	- 2 lb.	Improved under ordinary treatment.	After 1 mg. temperature was 101°, slight collapse. After 4 mg. temperature was 104°, marked collapse.
5	F., aged 22. Marked heredity.	Fair nutrition; temperature 99° F.; weight 105 lb. Sputum scanty; bacilli present. Consolidation of right apex; crepitations.	Feb. 20th, 1898: $\frac{1}{100}$ mg. May 8th, 1898: 6 mg.	Physical signs gone; cough gone.	+ 7 lb.	June 30th, 1898: in good health.	After 2 mg. temperature 105°; serious collapse.
6	M., aged 42.	Nutrition poor; temperature 101° F.; weight 115 lb. Sputum copious; bacilli numerous. Right apex consolidated; softening; thickened pleura.	March 1st, 1898: $\frac{1}{100}$ mg. May 8th, 1898: 4 mg.	Physical signs increased; temperature hectic.	- 8 lb.	June 30th, 1898: steadily getting worse.	Red corpuscles broke down; anæmia became more marked.
7	M., aged 40. Marked heredity.	Nutrition poor; temperature 101°F.; weight 109 lb.; sputum copious; bacilli present. Both apices consolidated; cavity left apex.	Never stood injections well.		- 3 lb.	June 30th, 1898: *in statu quo*.	—
8	M., aged 26.	Nutrition poor; temperature 101° F.; weight 97 lb. Sputum copious; bacilli present; both apices solid; softening.	March 18th, 1898: $\frac{1}{100}$ mg. 2 mg.	Sputum more abundant; temperature hectic.	- 1 lb.	June 30th, 1898: *in statu quo*.	After 1 mg. temperature was 102°.
9	F., aged 16. Marked heredity.	Nutrition poor; temperature normal; weight 84 lb. Sputum abundant; bacilli present. Right side apical consolidation; thickened pleura.	Feb. 25th, 1898: $\frac{1}{100}$ mg. May 8th, 1898: $\frac{1}{2}$ mg.	Temperature hectic; physical signs unchanged.	- 2 lb.	May 30th, 1898: wasting.	Treatment stopped as condition was becoming worse.
10	F., aged 19. Marked heredity.	Nutrition good; temperature normal; weight 150 lb. Sputum scanty; bacilli present. Left apex consolidation; early softening.	Feb. 20th, 1898: $\frac{1}{100}$ mg. April 10th, 1898: 5 mg.	Chest cleared up; no cough.	+ 10 lb.	May 30th, 1898: still in good health.	No reaction throughout.
11	F., aged 27. Marked heredity.	Nutrition fair; temperature 101° F.; weight 120 lb. Sputum scanty; bacilli present. Consolidation of both apices.	Feb. 20th, 1898: $\frac{1}{100}$ mg. April 12th, 1898: 4 mg.	*In statu quo*.	- 4 lb.	Left at own request.	—
12	F., aged 18.	Extensive unilateral lupus of face; five years' history. Weight 103 lb.; temperature normal.	Feb. 25th, 1898: $\frac{1}{100}$ mg. May 8th, 1898: 5 mg.	Soundly healed.	+ 11 lb.	May 30th, 1898: no recrudescence.	No reaction; marked local redness and scaling.
13	F., aged 16.	Lupus exedens of 12 years' duration; destruction of nose. Weight 53 lb.; temperature normal.	Feb. 11th, 1898: $\frac{1}{100}$ mg. May 7th, 1898: 1 mg.	Soundly healed.	+ 7 lb.	May 30th, 1898: no recrudescence.	No reaction; local reaction as in Case 12.
14	F., aged 14. Marked phthisical heredity.	Tuberculosis of iris; no pulmonary lesion. Temperature normal; weight 67 lb.	March 13th, 1898: $\frac{1}{100}$ mg. May 8th, 1898: $\frac{1}{2}$ mg.	Conjunctivitis and iritis.	+ 12 lb.	Left hospital; general condition much improved.	After $\frac{1}{2}$ mg. marked local reaction.
15	F., aged 30. Marked heredity.	Nutrition fair; temperature 99° F.; weight 69½ lb. Bacilli present. Left apex consolidation; thickened pleura.	Feb. 1st, 1898: $\frac{1}{100}$ mg. May 8th, 1898: 8 mg.	Physical signs the same; cough less; sputum absent; bacilli still present.	+ 6 lb.	Still in hospital, improved.	Treatment stopped on account of pleuropneumonia.
16	M., aged 44.	Nutrition poor; weight 100 lb.; temperature 100° F. Bacilli present; consolidation at both apices.	Feb. 11th, 1898: $\frac{1}{100}$ mg. April 20th, 1898: 6 mg.	Reactions constant; physical signs improved.	+ 5 lb.	No real improvement; cough still severe; bacilli present.	*In statu quo*.

Of the above 16 cases 15 were treated in Mill-road Infirmary.

Digitized by Google

immunity and when its action is complete the injection of the old tuberculin causes no reaction." "The fluid is preserved by the addition of glycerine (20 per cent.) and 1 c.c. is equivalent to 10 mg. of solid substance." "The syringe used must not be sterilised with carbolic acid and the necessary dilutions are to be made with normal saline solution." "Dosage.—It is best to begin with $\frac{1}{500}$ mg. of the solid substance; injections may be given every second day, the dose being slowly increased, but so slowly that a rise of temperature of more than 0·5°C. is never seen. Should any rise occur it must subside before a further dose is given. The final dose, as a rule, is 20 mg. and when this is reached without reaction then further injections are not given or only given at long intervals."

Omitting the experiments on animals we have the following statement: "In man immunity is present *only* when doses of 0·5 to 1 milligramme are reached, and consequently *tuberculin R. is not available for treatment when the patient's prospect of life is only a few months.*" "*In cases of mixed infection the remedy is of little use, and Koch states that cases with higher temperature than 38° C. (100·4° F.) are only exceptionally suitable.*" (The italics are ours.)

In pulmonary tuberculosis the effect of the injections is given as follows: "No general reaction occurs, simply a little increase in the adventitious sounds, the sputum soon diminishes in amount, and the tubercle bacilli disappear, the physical signs improve, weight is gained from the beginning, and the temperature regains the normal level."

It is difficult—nay, almost impossible—to obtain in hospital practice a series of cases of tuberculosis exactly conforming to the requirements of Koch for treatment by tuberculin R. Patients with symptoms least distant from the very early stages of tuberculosis were treated, and in some cases where the disease was more advanced an amelioration of symptoms was all that was hoped for. In 4 cases not included in the table with high temperatures the result of mixed infection the symptoms were in no way improved; in fact, in some they were aggravated, so that the treatment was not continued.

Results.—In 13 cases of phthisis pulmonalis subjected to no other treatment but injections of tuberculin and ordinary diet 4 were completely cured—viz., Nos. 1, 3, 5, and 10. They have all gained in weight, the physical signs noted on admission have disappeared, the tubercle bacilli are absent, and the patients have left the hospital, and at the time of writing they are quite well. In Case 2 the treatment was stopped as the disease steadily progressed and weight was lost. In Case 4 severe reactions followed the injection of 4 mg. on three occasions, and as weight was lost the treatment was given up. In Cases 6 and 7 reactions followed the smaller doses and as weight was steadily lost the treatment was abandoned. In Case 9 the whole of the right pleura was thickened, the patient became hectic and she lost weight. In Case 11, no alteration for better or worse occurring, the treatment was abandoned when immunity doses had been reached. In Case 8, which was hardly a suitable case, reactions were early and severe and the treatment was abandoned on reaching 1 mg. In 7 cases the blood corpuscles were counted whilst the treatment was being carried out. In 2 the number of red cells were increased, in 5 diminished; in 4 cases the white cells were increased and in 3 diminished.

The lupus cases were undoubtedly benefited, all being chronic intractable cases which had resisted all ordinary measures. They have all healed soundly and at the time of writing have not broken down. The patient with tuberculosis of the iris was of great interest as the lesion was in a very vascular part and was open to observation. The specific action of the tuberculin was manifest from the earliest dose and it is regrettable that from the extent of the local reaction the treatment had to be abandoned.

General conclusions.—From a very careful observation of the effects of tuberculin R. given alone in doses as prescribed by Koch and not accompanied by any other treatment on cases of phthisis pulmonalis we are able to announce four cases of complete recovery out of thirteen cases treated. These four cases were the most favourable for treatment, as the disease was localised and the temperatures were not such as to suggest mixed infection. We feel that this result is little if any better than that of ordinary treatment combined with nourishing diet and good hygienic surroundings. In the lupus cases, on the other hand, we feel we have a powerful and useful means of treatment. In cases of phthisis it is evident that even with great care in the regulation of the dosage reactions do occur and the general collapse which followed 1 mg. in Case 5 was most alarming. It is possible that the explanation of this is due to the fact that the solutions of tuberculin R. are not of uniform strength throughout.

Liverpool.

THE TREATMENT OF FIBROMYOMA OF THE UTERUS.

BY J. INGLIS PARSONS, M.D. DURH., M.R.C.P. LOND.,
PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

PERHAPS there is no disease so varied in its manifestations as fibromyoma of the uterus. In one case a tumour is accidentally discovered, which causes no symptoms whatever; in another the patient presents every appearance of having malignant disease and is totally incapacitated for work. Of all the different symptoms which we have to combat hæmorrhage and pain are the most prominent. The former, beginning with a slight menorrhagia and gradually increasing for one or two years until in some cases it attains to a continued metrorrhagia completely exhausting the patient, is very characteristic of this disease. This can hardly be said of the pains, although with these again there is a great difference between the slight discomfort experienced by some and the severe distress complained of by others. Intermittent in character they vary with the size and position of the tumours and the pressure exercised on the nerves and structures within the pelvis and abdomen. The most common of all resembles a labour pain in a minor degree. Produced by the contractions of the uterus it may be regarded as a natural effort of this organ to rid itself of an unwelcome visitor. But it is none the less wearing to the patient and requires the earnest attention of the physician. Besides hæmorrhage and pains we find a variety of other symptoms which are more serious and are produced by the pressure of the tumours on important viscera—viz., irritable bladder and retention of urine, difficulty in defecation from pressure on the rectum, œdema of the lower extremities from pressure on the iliac veins, and loss of power in the legs from pressure on the sacral plexus. The ureters appear able to adapt themselves and nearly always escape. Hydronephrosis from the pressure of a fibroma is rare. Pelvic peritonitis is not uncommon with an effusion of lymph fixing the tumour and obscuring its shape. The uterus itself is always enlarged more or less, sometimes to an enormous size. Certain changes take place in the endometrium. There is generally glandular endometritis present, which may lead to the formation of an adenomatous polypus. In addition to this, whenever a tumour or a portion of it is submucous there is an interstitial as well as glandular endometritis with thick-walled vessels and a greatly dilated capillary network. It is this vascular condition of the endometrium or a polypus which causes the hæmorrhage.

The diagnosis is usually very easy, but occasionally very difficult. The typical case is a single woman between thirty and forty years of age or a married woman who is sterile or has not had children for many years, complaining of increasing menorrhagia and occasional pains in the abdomen. On examination an enlarged hard nodular uterus is easily felt. The diagnosis is then certain. But when there is a large, soft, elastic and semi-fluctuating mass, with the uterus pushed out of position, a difficulty will arise. Perhaps it is impossible to pass the sound and there may be no history of menorrhagia. Even in these cases a correct diagnosis may often be arrived at although the physical signs are nearly the same for a multilocular ovarian tumour. An examination under an anæsthetic should always be done in doubtful cases. If the tumour is ovarian the growth is generally more rapid. The history may show that it started on one side of the pelvis. The uterus is separate instead of forming part of the swelling and not as a rule enlarged. Menorrhagia is not a prominent symptom and the tumour is smoother than most myomata. Just as there are great differences in the size, symptoms and gravity of fibromyoma so also is there great variety in the treatment to be adopted. Each case must be considered on its individual merits. Many cases require no treatment whatever. In the early stages when the only symptom is a

Digitized by Google

slight increase in menstruation medicine should be given a fair trial. Of the various drugs used the most valuable in my experience is ergot and the preparation of it which I prefer is the fresh British Pharmacopœia liquid extract given in drachm doses two or three times a day in chloroform water after food. Hydrastis canadensis in my experience is very inferior to ergot, but is worth trying when ergot fails. Nux vomica and quinine are also of some value. Bromide of potassium and Viburnum prunifolium help to restrain the loss and ease the pains. The subcutaneous injection of ergotin I have quite discarded because other measures not more painful, but more efficacious, can be adopted.

After the publication of Dr. Jouin's paper on the Influence of Thyroid Extract on Fibromyoma I gave the drug a fair trial in five cases. Four of these were women of about the age of forty years with old hard fibromata of many years' standing. No appreciable diminution in size followed after a three months' course, but in the fifth case sent to me by Mr. Hildyard Rogers in 1896 there was a distinct reduction in size. The patient, a single woman, aged twenty-five years, had a large hard nodular fibromyoma almost filling the pelvis and dipping down into Douglas's pouch. The cervix was drawn up and pressed against the pubes. She suffered from morning sickness and attacks of retention which had to be relieved with a catheter. These symptoms disappeared after a three months' course of thyroid extract. The tumour distinctly diminished in size. Mr. Hildyard Rogers, in answer to my inquiries, wrote in January, 1898: "I certainly think the tumour has diminished in size and in any case it certainly has not increased and she has been quite free from the troubles which she had before and is in fairly good health." The value of saline aperients in relieving the congestion of the pelvic vessels is not appreciated as much as it should be. A full dose of Rubinat, Hunyadi, or Friedrichshall taken every other day before breakfast so as to produce a watery evacuation gives considerable relief. When, however, the menorrhagia persists and increases in spite of medicines other measures must be considered. If the uterine canal is fairly patent a simple and temporarily efficacious proceeding is to swab it with a probe covered with cotton-wool dipped in liquor ferri perchloridi fortior. I have never seen any harm result from doing this, while the hæmorrhage is always stopped for a time. It very often happens that the probe cannot be passed up without squeezing most of the solution out at the external os. Under these circumstances dilatation becomes necessary and a better result will then follow from the use of the curette. The removal of the diseased endometrium already described produces an abatement of symptoms which will last for some months, but neither in my own practice nor in the practice of others have I ever seen a permanent result follow. The menorrhagia returns and we must either curette again or adopt some other treatment which will produce a more permanent result. When dilatation has been done we may find a small fibroid polypus in the uterine cavity which is the chief cause of the hæmorrhage. This is easily removed with the serre-nœud. But if the tumour is at all large or is sessile or has a very thick pedicle considerable difficulty may be encountered. Very often it is necessary to split the cervix on each side and remove the tumour piecemeal. Unless there is a distinct pedicle it is better to temporise than to attempt enucleation. The fibroma is generally firmly embedded and held by adhesions. The amount of force necessary to drag it out may even cause inversion or rupture the wall of the uterus. There is always profuse hæmorrhage. By waiting and giving ergot or with the help of electricity the tumour will become more extruded and can then be removed with much less risk at a later date. There will always remain a large proportion of cases in which the above measures produce no permanent result. We can then fall back on electricity. About 80 per cent. of all cases can be treated with great benefit, without appreciable risk and without mutilation of the sexual organs and without having to lay up.

It has been urged against electricity that the tumour is not got rid of. If we once admit that some cases having no symptoms require no treatment, this argument falls to the ground because it admits that the presence of the tumour does not matter. The female pelvis, being adapted by nature to contain an enlarged pregnant uterus without interference with the general health, very well tolerates an enlargement from other causes. Although Apostoli's method is now well established it may not be out of place to describe a few severe cases treated by this method. Hæmorrhage can always be stopped if an electrode can be passed. A patient under the care of the late Dr. Edis and one of the first whom I treated came to see me last year. In 1887 she was obliged to take to her bed from continued hæmorrhage in spite of ergotin injections and previous curetting. After thirty applications the loss was reduced to normal. She came to see me in 1897, ten years after the treatment was applied. There has never been any return of the hæmorrhage. In 1895 the menopause ensued and the tumour is now of about half the size and only reaches to the level of the pubes instead of to the umbilicus.

In my last list of cases[1] I described one case where a permanent cessation of hæmorrhage had not followed. This patient came to me subsequently in 1895 and told me that the metrorrhagia had gradually left off; she has since been quite regular. In July, 1894, Sir Francis Laking asked me to see a patient, aged thirty-nine years, with profuse hæmorrhage commencing eighteen months previously. The uterus was enlarged and two small fibromata could be felt in the fundus. She was unable to leave her bed and was so ill and anæmic that her appearance suggested malignant disease. After seven applications the hæmorrhage was stopped. Eighteen applications in all were given and full doses of iron to combat the anæmia. I heard from Dr. Vernon-Jones, who took charge of her with me during the treatment, that she is now (after four years) in excellent health and has had no return of the hæmorrhage. In July, 1896, Dr. Braxton Hicks sent a woman, aged thirty-six years, to me for profuse hæmorrhage. The tumours reached to the umbilicus and also involved the cervix uteri. There were œdema of the ankle and great weakness from the hæmorrhage so that she had to be taken to a nursing home. After five applications the loss was much reduced and she was able to leave the home. Twenty-one applications were given altogether and the loss has been quite regular and normal in quantity since. This patient wrote from the country as follows: "January, 1898: I am very well and wish I could call just to show you the thoroughly satisfactory result of your treatment. It has been a very jolly autumn; life seems such a different thing when one feels perfectly well and strong."

Of all the cases I have treated for hæmorrhage since the publication of my last paper only one has had any return after the treatment. This was a woman, aged thirty years, who came to me in April, 1896, a patient under the care of Dr. R. H. Barkwell. There were two small tumours—one in the fundus and one in the anterior wall. After nineteen applications the loss was reduced to normal, but it began to increase again in a few months. Seven more applications were given, beginning in February, 1897. After a lapse of five months the treatment was then interrupted again for six months on account of a varicose ulcer which laid her up. Now (February, 1898), after twelve more applications, the loss is again normal and I have hopes will remain so. In addition to the arrest of the hæmorrhage by electricity pressure symptoms can also be abolished or relieved in suitable cases. An instance of this was a patient under the care of Mr. Allt of Clapham. She was a single woman, aged thirty-nine years, with a very large tumour reaching up to the ribs. She suffered from severe pains in the abdomen and left leg, with œdema of the ankles, varicose veins and slight menorrhagia. The sound passed 8½ in. She was unable to do any work and had become a chronic invalid. The treatment was commenced in 1897 and after fifteen applications all her symptoms had gone. I saw her in January, 1898; she is now able to work well, all the pains have disappeared, there is no œdema of the ankles, menstruation is quite regular and the loss is normal in quantity. On examination the tumour was reduced by 2 in. in length and very materially in girth. She was delighted with herself and told me that Mr. Allt was also very pleased.

Another patient, a woman aged thirty-five years, had suffered for eighteen months from bladder irritation and repeated attacks of retention of urine and severe pains in the abdomen. The uterus was hard and nodular, reaching half way to the umbilicus. She was admitted into the hospital on Feb. 13th, 1897. After sixteen applications her symptoms had all gone. During my absence from influenza in January, 1898, Dr. Berkeley, physician to out-patients, saw her at the

[1] THE LANCET, Feb. 27th, 1892.

Digitized by Google

hospital and found her very well and without any return of the bladder trouble.

In suitable cases with electricity hæmorrhage can be stopped, the pressure symptoms and pain can be got rid of and the tumour reduced in size and this without the patient having to run any appreciable risk or suffer any mutilation of her sexual organs. Some cases are unsuitable—viz.: (1) fibrocystic tumours growing rapidly in young subjects; (2) old hard tumours composed chiefly of fibrous tissue; (3) associated disease of the tubes and ovaries; and (4) very large tumours. With these cases the question of abdominal section must be faced when there are severe or urgent symptoms. I must say that with the help of electricity and other treatment already described I do not often find this necessary.

There are four procedures which can be adopted, according to the case before us—myomectomy, enucleation, castration, and hysterectomy. Myomectomy is only feasible with subperitoneal tumours which have become more or less extruded from the uterine tissue and present some approach to if not a well-defined pedicle. Such cases are uncommon and when they do occur may produce no symptoms. In nearly every case the tumour is embedded in the uterine walls and can only be got out by enucleation if we wish to save the sexual organs. This operation has been chiefly supported by Schröder, but is to a great extent discarded on account of its high mortality, higher even than hysterectomy. The cavity from which the tumour has been dug out very often cannot be properly closed up. There is consequently great difficulty in restraining hæmorrhage, while the accumulation of discharges within the cavity is likely to cause peritonitis. Among practical men the choice in almost every case requiring abdominal section lies between removal of the ovaries and hysterectomy. It is unfortunate that the tumour can rarely be removed without mutilation of the sexual organs. Castration is not always feasible nor are the results always successful. Menstruation may continue and severe hæmorrhage, necessitating further treatment. The risk of the operation in suitable cases is not great. The chief point in operating is not to leave a scrap of ovarian tissue behind and to take the tubes away as well. When it is not possible to remove the ovaries hysterectomy must be done. According to Pozzi the mortality of the leading operators based on over 600 published cases is 21·6 per cent. for the extra-peritoneal operation and 25·7 per cent. for the subperitoneal operation. Since the publication of these statistics the latter operation has been much improved and probably has a lower mortality than the former.

We must, however, bear in mind that hysterectomy still has a higher mortality than any other operation in gynæcology, while it is performed for a disease which if left alone is very rarely fatal and which will in all probability cure itself in middle age. In addition to this it cannot be done without mutilation of the sexual organs. The opinion of one of the greatest surgeons of the century and the most successful in this operation, Thomas Keith, is worth quoting—viz.; "I often ask myself the question, Does a mortality of 8 per cent. justify an operation for a disease that as a rule has only a limited active life, that torments simply, and that only for a time, though of itself it rarely kills? The mortality of an ordinary uterine fibroid if left alone is nothing approaching a death-rate of 8 per cent. I doubt even if the mortality of the extreme cases exceed this. And, after all, the great difficulty is not in doing even the worst of these operations, but in knowing what are the cases in which it is right to advise those who trust themselves to us to run the risk of a dangerous operation with all its attendant miseries. Could we get the mortality down to 5 per cent. in the bad cases—and these only are the fit subjects—then one might advise interference with a more easy mind." These words of wisdom sum up the subject perfectly. I have very often found that the public confused ovariotomy with hysterectomy. In all cases it should be explained that an ovarian cyst is invariably fatal if left, while the operation is not very dangerous, and the sexual organs with one ovary left will continue their functions, whereas a fibromyoma is very rarely fatal if left, while the operation is much more dangerous than ovariotomy, and for a certainty means a mutilation of the sexual organs. If after these facts are made perfectly clear to the patient and she still wishes to undergo hysterectomy when other treatment has failed to relieve her then I think we are justified in performing the operation.

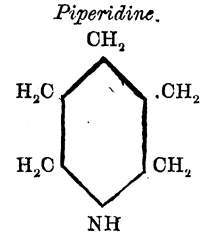
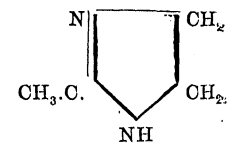
PIPERIDINE AS A URIC ACID SOLVENT: A COMPARATIVE STUDY.



BY F. W. TUNNICLIFFE, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION;
AND
OTTO ROSENHEIM, PH.D., F.C.S.

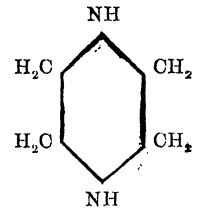
WE have elsewhere[1] drawn attention to the solubility in water of piperidine urate and to the molecular constitution of this salt.[2] In the first of these papers we stated that experiments were in progress with the object of ascertaining whether this remarkable property of piperidine could be utilised in medicine. This subject must obviously be studied from two points of view—namely, (1) chemical and pharmacological; and (2) clinical. As we have now completed the first part of this research we consider it better to give shortly our results although the second part of the investigation is not at present complete. For the sake of clearness we propose to consider this subject under the following headings: I. Chemistry. II. Conditions which must be fulfilled by any drug to justify its therapeutic use in the uric acid diathesis, including under this head gout. (*A*) Proof of the non-poisonous nature of the drug in doses equivalent to those in which it would have hypothetically to be administered; (*B*) the demonstration of the drug as such in the urine; (*C*) the property of dissolving (*a*) uric acid (on the distal side of the excreting membrane of the kidney), (*b*) urinary sediment,[3] and (*c*) sodium biurate in the blood. Under (*C*) we shall compare the power of piperidine to that of other known uric acid solvents.

I.—CHEMISTRY.



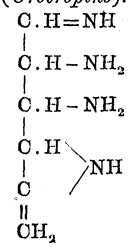
Under this heading it is interesting to note that the structural formulæ of the various uric acid solvents show a certain resemblance. Our research in this connexion has been confined to the following substances, of which we subjoin the structural formulæ;—

Piperidine.



(Pyridine-hexahydrine.)

Lysidine.



(Methyl-glyoxalidine.)

Piperazine.

(Pyrazine-hexahydrine.)

Hexamethylene Tetramin[4] *(Urotropine).*

This relationship is more apparent in the case of the first three bodies than in that of the fourth. Each, however, of the substances possesses one or more NH (imine) groups

[1] Brit. Med. Jour., Feb. 27th, 1897.
[2] Centralblatt für Physiologie, Band iii., p. 434.
[3] With regard to the chemical nature of the urinary sediment we have not been able to convince ourselves of the existence of the so-called quadriurates. A further discussion here would be beside our purpose.
[4] This formula is the one recently advanced by Georg Cohn (Journal für Praktische Chemie (2), lvi., p. 345, 1897) and seems to accord better with all the known chemical reactions of this substance than the earlier formulæ.

Digitized by Google

and further one or more CH_2 groups.[5] The first three are to be regarded as ring compounds; this in the case of the last one is doubtful. The first three may further be regarded as completely (piperidine and piperazine) or partially (lysidine) reduced bases. All four possess basic properties of varying strength. The uric acid solvent power seems to be dependent upon the presence of the NH group, but does not seem directly proportional to the number of these groups. For instance, as we shall subsequently see, piperidine (one NH group) has an incomparably greater solvent power than piperazine (two NH groups), whereas lysidine (also containing one NH group) likewise as a solvent greatly exceeds piperazine (two NH groups) but in certain instances falls short of piperidine. With regard to the constitution of the salts formed by the action of these bases upon uric acid we have more especially studied the piperidine urate. It is formed by the interaction of piperidine and uric acid in molecular proportions in aqueous solution, from which it is precipitated by alcohol and ether as a white crystalline powder. By re-crystallisation from a small volume of water it may be obtained in the shape of well-defined colourless cubes. It is characterised by its solubility in water, which amounts at blood temperature to 9·1 per cent. For further chemical details readers are referred to earlier papers of the authors.[6]

The constitution of lysidine urate is given by Professor Ladenburg[7] as being $C_4H_8N_2$ ($C_5H_4N_4O_3$); that of piperazine urate by Majert and Schmidt[8] as being $C_4N_2H_{10}$ ($C_5H_4N_4O_3$). In the case of urotropine the compound or compounds formed seem to be of a more complicated nature and do not seem as far as we are aware to have been specially studied.[9] Under the circumstances we consider it of interest to briefly describe our own observations in this connexion. If hexamethylene-tetramine be allowed to act upon uric acid in the presence of water a clear solution is obtained at boiling temperature which forms into a transparent gelatinous mass upon cooling. When the compound formed is precipitated from the solution by alcohol and ether or by acetone it forms an opaque gelatinous mass. In both cases filtration is very difficult. When dried at blood temperature or in vacuo it forms a white amorphous powder, which on being dissolved in hot water and subsequently submitted to cooling is precipitated again in the form of a gelatinous mass. When a solution of this substance is evaporated on a water bath formic aldehyde is set free, thus indicating the partial decomposition of the urate. From the above experiments the obvious inference is that hexamethylene-tetramine urate belongs to the class of substances known as colloids. But it was found on submitting the substance to dialysis that it, unlike colloids, dialysed freely and could be re-obtained from the dialysate in a gelatinous form. This colloid-like form of urotropine urate is of interest in connexion with the experiments of Dr. Ord[10] on colloid urates. The dialysability of these latter and their significance with regard to the natural excretion of urates in birds and serpents have already been pointed out by Sir William Roberts.[11]

II.—CONDITIONS WHICH MUST BE FULFILLED BY ANY DRUG TO JUSTIFY ITS THERAPEUTIC USE IN THE URIC ACID DIATHESIS, INCLUDING UNDER THIS HEAD GOUT.

A. Proof of the non-poisonous nature of the drug in doses equivalent to those which would hypothetically be required.—The physiological action of piperidine on the lower animals has been studied by Fliess,[12] A. Heine,[13] A. Gürber,[14] Öchsner de Coninck and Pinet,[15] R. Thielmann,[16] Cushny,[17] Tunnicliffe,[18] and B. Moore and R. Row.[19] These observations, although of extreme interest from a pharmacological standpoint, are not germane to the subject of this paper. As far as we are aware no observations have been recorded with regard to the action of this substance on man. One of us published some results obtained with the guaiacolate of piperidine in phthisis.[20] These patients took as much as 25 grains three times a day, corresponding to 20 grains of piperidine per diem, without any unpleasant effects ensuing. We have also taken ourselves a quantity of the tartrate of piperidine corresponding to 1 gramme (= 15 grains) of piperidine for eight consecutive days without experiencing any symptom. Patients under our care have also taken quantities of the tartrate or carbamate corresponding to from 1 to 1½ grammes (from 15 to 22 grains) of piperidine per diem without any effect. In one case the drug was pushed in order to see what would be the nature of the symptoms corresponding to an overdose. The patient in question took upon an empty stomach at 10 P.M. 15 grains (1 gramme) of the carbamate of piperidine—i.e., 0·7 gramme of piperidine—and repeated this dose at 6 A.M. in the morning also on an empty stomach. About one hour later he experienced a feeling of nausea accompanied by gastric distension. This did not, however, culminate in vomiting. No nervous symptoms of any kind occurred and no diarrhœa. The symptoms soon began to abate and four hours after the second dose had entirely disappeared. This result in man entirely confirms the unpublished results of one of us upon the lower animals, which show that the salts of piperidine in relatively large doses acted as a central emetic, stimulating the vomiting centre in the medulla.[21]

Hypodermic injections in man of carbamate and hydrochlorate of piperidine in quantities corresponding to from 0·1 to 0·3 gramme of piperidine produced no general symptoms whatever, but gave rise to slight local irritation. When, however, the injections were intra-muscular this did not take place. In the early physiological experiments which we made with piperidine we used the hydrochlorate. Subsequently Dr. Schidrowitz drew our attention to, and prepared in a pure form, the salt, which is formed by the action of carbonic acid on piperidine and which is to be regarded as the carbamate. This forms a very serviceable salt and possesses many advantages, of which the relatively high piperidine percentage is perhaps the chief. It occurred, however, to us, in conjunction with Dr. Schidrowitz, that a combination of the diuretic and antacid action of tartaric acid, in combination with the uric acid solvent power of piperidine, would be a distinct desideratum. We therefore prepared the acid tartrate of piperidine, which can be obtained in well-developed crystals. This salt is easily soluble and has a pleasant taste and can be given in doses of 10 grains or more from three to four times a day after meals. The average quantity of uric acid excreted per diem in man is 0·8 g.[22] The theoretical amount to convert this into a soluble form—namely, piperidine urate—is 0·4 gramme piperidine. From experiments which will be detailed later it will be seen that piperidine keeps in solution in urine a little over its own weight of uric acid. Since 1½ grammes of piperidine may be taken per diem without any unpleasant effect ensuing and only about half of this amount is necessary to keep the average diurnal quantity of uric acid in solution, there seems to be a sufficient margin allowed for the quantitative relation between the ingestion and excretion of the drug.

B. The demonstration of the drug as such in the urine.—One of the spheres of action of a uric acid solvent lies on

[5] It is interesting to note that a similar action is exerted also by several alkaloids which contain reduced pyridin = or pyrrolidine = rings—i.e., an NH group in connexion with several CH_2 groups. As examples we may give nicotine, coniine, atropine, &c. For a complete and up-to-date account of the chemistry of these alkaloids see A. Pictet, Constitution des Alcaloids, 1897. That atropine very probably contains a pyrrolidine ring has only been recently shown by R. Willstätter, Berichte der Deutschen Chemischen Gesellschaft, Band xxx., p. 2679.

[8] Ibid., Band xxiii., p. 3718.

[9] The compounds formed by the action of formic aldehyde upon uric acid have been described by Tollens, Weber and Pott (Berichte der Deutschen Chemischen Gesellschaft, Band xxx., p. 2514), and the suggestion made that urotropine acts in a similar way to formic aldehyde. The exact proof of this seems wanting. Recent views with regard to the constitution of urotropine would seem to argue against this hypothesis.

[21] It may be of interest here to note that the emetic action of nicotine, well known to juvenile smokers, is also due to stimulation of the vomiting centre in the medulla and not to a local action on the stomach. Coniine in equivalent quantities has no central emetic action.

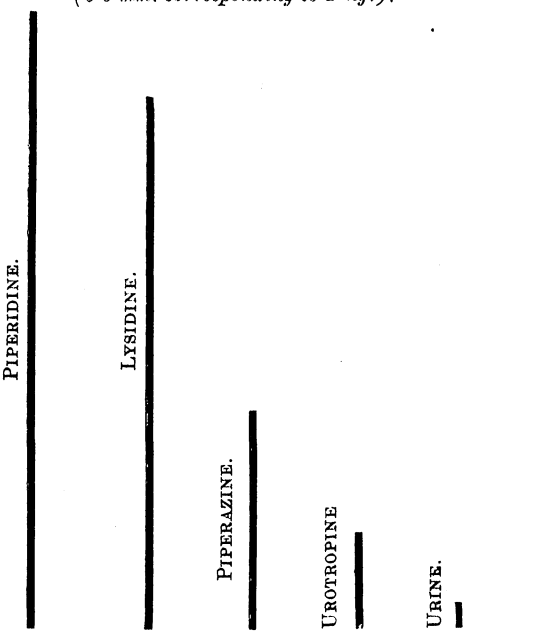
the distal side of the kidneys. By the distal side of the kidneys we mean the urine from the point where it leaves the secreting membrane of the kidney to its final evacuation. If any drug, whatever may be its solvent power upon uric acid in the test tube, does not leave the kidneys as such we are not justified in ascribing to it a uric acid solvent power in the urine. The importance of this has been recognised by all workers in this field of research. After a dose by the mouth of piperazine, lysidine, and urotropine the presence of these substances has been demonstrated in the urine.[23] In the case of piperidine we were able to demonstrate the presence of this substance in the urine one hour after a dose of 0·7 gramme (10 grains) of the tartrate. We were also able to demonstrate its presence 4½ hours after this dose. The whole of this amount seemed to be eliminated before the expiration of 48 hours, as at the end of this time we were no longer able to find it in the urine. The method which we used was based upon the property of this substance to form a characteristic well-crystallised compound with potassium-bismuth-iodine solution.[24] 100 c.c. of the urine were made alkaline with potassium hydrate and distilled. From 40 to 50 c.c. of the distillate were acidified with hydrochloric acid and evaporated to dryness on the water-bath. The white residue of the hydrochlorates was extracted with a few c.c. of absolute alcohol in which the hydrochlorate of piperidine is easily soluble. To the warm concentrated alcoholic extract a few drops of potassium-bismuth-iodine solution were added. Upon cooling the piperidine compound crystallised out and could be easily identified under the microscope by the characteristic form of the crystals. By slow crystallisation large, thin, transparent yellow hexagonal plates were obtained, which were occasionally superposed. When the crystallisation was allowed to take place more rapidly smaller crystals of the same kind were obtained. These results were controlled in two ways. First by the fact that normal urine treated as described above with bismuth-potassium-iodine solution gave no such crystals. Secondly, by the fact that urine to which piperidine had been added in the proportion of 0·1 per cent. showed under similar treatment crystals identical with those which were obtained from the urine after the administration of the piperidine by the mouth. We are not at present able to state the exact quantitative relation which exists between the amount of piperidine ingested and the amount excreted. We are, however, in connexion with our clinical researches, directing our attention to this subject.



C. The property of the drug of dissolving (a) uric acid on the distal side of the excreting membrane of the kidney.—In order to test this point a set of experiments was made in which the amount of uric acid was estimated which was kept in solution by a certain amount of the drug in a certain quantity of urine. In each case the dissolving mixture consisted of 100 c.c. of mixed normal human urine, 0·5 gramme of pure uric acid[25] and 0·2 gramme of the solvent. The mixtures were placed in an incubator for six hours at blood temperature and frequently shaken. After that time the undissolved uric acid was filtered off and the uric acid estimated in the filtrate by our own method.[26] Three simultaneous experiments were made in each case and the average was taken. The drugs used were: piperidine, lysidine, piperazine, and urotropine. A set of control experiments was made simultaneously. The solvent mixture in this case consisted of a 100 c.c. of the mixed urine and 0·5 gramme of uric acid. The mixed urine used for these experiments had the following properties: specific gravity (15° C.), 1·0204; acidity,[27] 2·7; mineral matter, 1·4 per cent.; and uric acid, 0·0636 per cent. The results of these experiments are best shown by the following table.

TABLE I.—*Showing the Influence of 0·2 per cent. of certain Bases on the Solvent Power of Urine for Uric Acid.*

Quantity of urine.	Quantity of solvent.	Solvent used.	Quantity of added uric acid.	Quantity of uric acid kept in solution.	Original quantity of uric acid in the urine.	Quantity of uric acid kept in solution over and above that originally present.	Solvent power in terms of

The property of the drug of dissolving (b) urinary sediment.—As urinary sediments consist of a mixture of uric acid and urates in varying proportions it is obvious that the results obtained above with pure uric acid are not strictly applicable to urinary sediment as it exists in man. We therefore next directed our attention to this point and proceeded as follows. A large quantity of urine possessing deposits of uric acid and urates was collected from different patients in St. Bartholomew's Hospital. Ten litres of urine were so collected and kept preserved by the addition of a few drops of chloroform or a crystal of thymol.[28] Eight litres were filtered and the deposit was rinsed into the remaining two litres by means of the same urine. The resulting liquid was well shaken and had the following characteristics: specific gravity (at 15° C.), 1·0146; acidity, 1·96; mineral matter, 0·68 per cent.; total uric acid, 0·1267 per cent.; and uric acid in solution, 0·0326 per cent. Five sets of experiments were made with this urine artificially saturated with natural sediments, each set consisting of three experiments. The solvent mixture consisted in each case of 0·1 gramme of the respective drug and 100 c.c. of the urine. One set of experiments were controls consisting of the urine alone. In order to ensure an even dissemination of the sediment the

[24] Cf. Kraut: Liebig's Annalen, Band ccx., p. 310, where also the quantitative composition of the reagent is given, which was found to be more sensitive for this purpose than Drachendorf's reagent (vide also Berichte der Deutschen Chemischen Gesellschaft, Band xxix., p. 2065).

[25] For the preparation of uric acid the pure commercial product was further purified by Bensch's method (Liebig's Annalen, Band liv., pp. 190–193) through the potassium salt or in some cases through the piperidine salt.

[26] Loc. cit. In cases where the quantity of uric acid to be determined is very small we found it advantageous to use a $\frac{1}{10}$ normal piperidine solution, 1 c.c. of which corresponds to 0·00336 gramme of uric acid. When using so sensitive a solution the error produced by the slightly acid reaction of filter paper or distilled water must be taken in regard. This error was estimated once for all for a certain size of filter paper and the amount of water used by means of comparative experiments. The amount required for the correction was 0·12 c.c. of a $\frac{1}{10}$ normal piperidine solution. For the estimations a normal pipette was used, which allowed the reading 0·01 c.c.

[27] The acidity in this paper is always expressed as the number of c.c. of $\frac{1}{10}$ normal KOH solution required to neutralise 10 c.c. of the urine, using phenolphtalein as an indicator.

[28] Our first idea was to use formic aldehyde for this purpose, as it possesses very great disinfecting powers in minute quantities. It has, however, a marked solvent action on uric acid and in order to eliminate this source of error we used chloroform or thymol.

stock of urine was kept constantly stirred while the necessary quantities were measured out by a pipette. The solvent mixtures were kept in the incubator for 2½ hours at blood temperature and were then left to stand in a cool place for 24 hours. After that time they were filtered and the uric acid kept in solution was estimated as before.

TABLE II.—*Showing the Influence of 1 per cent. of certain Bases on the Solvent Power of Urine for Urinary Sediments.*

Graphic Representation of the Results expressed in Table II. (1 mm. corresponding to 1 mg.).

If we compare the results obtained in the case of pure uric acid added to urine with those in which natural urinary sediment was used we shall see that the quantity dissolved by piperidine and lysidine in the latter case is exactly the same as in the former, taking in consideration the fact that in the former case double the quantity of solvent was used. In both cases the solvent power exerted by piperidine and lysidine is greatly in excess of that exerted by piperazine and urotropine. The only difference between the two sets of results is that in the case of urinary sediments the solvent powers of the urine, piperazine, and urotropine were relatively to piperidine and lysidine greater than in the case of uric acid. The results are further of interest in that they show that the solvent power of piperidine and lysidine is directly proportional to the amounts used even in relatively dilute solutions. Since the urinary sediment consisted of uric acid and urates it appears from these experiments that piperidine and lysidine exert a solvent power upon such a mixture in the presence of urine equivalent to that which they exert upon pure uric acid. In the case of piperazine and urotropine this action seems greater in the case of the mixture than in that of pure uric acid.

The property of the drug of dissolving (a) sodium biurate in the blood.—For the purpose of studying this question we prepared according to Sir William Roberts's directions a so-called standard solvent which contains in 100 c.c. distilled water 0·5 gramme sodium chloride and 0·2 gramme sodium bicarbonate. According to Sir William Roberts this solvent behaves towards sodium biurate exactly the same as blood serum.[29] The solvent power of the standard solvent upon sodium biurate was estimated by Sir William Roberts and is given as probably 1 in 10,000. No details are, however, described of the experiments which led to this conclusion. From experiments made by Dr. Luff[30] it appears, however, that sodium biurate is soluble in unaltered serum to the extent of 1 part in 20,000 (0·05 gramme in 1000). From this it is obvious that there is a very considerable difference between the solubility of sodium biurate in standard solvent as calculated by Sir William Roberts and its solubility in serum as ascertained by Dr. Luff. This discrepancy made us consider it worth while to test the solvent power of both these media upon sodium biurate before studying the effect of the addition of small quantities of certain bases in this direction. We shall first direct our attention to the standard solvent.

The solubility of sodium biurate in standard solvent.[31]—In determining the solubility in standard solvent of so relatively insoluble a salt as sodium biurate it is obvious, temperature being constant (38° C.), that two factors of considerable importance are time and volume. With regard to time the longer the exposure the more dissolved up to a certain limit. With regard to volume the relation is not so simple and depends upon the extent to which by means of agitation fresh layers of the solvent can be brought into contact with the substance to be dissolved. As we convinced ourselves by preliminary qualitative experiments that the solubility of sodium biurate in standard solvent is very small indeed we, in accordance with ordinary physical method, took relatively large quantities (500 c.c.) of the solvent.[32] Five separate sets of experiments were made. The first consisted in taking 4 flasks containing 500 c.c. of standard solvent each, adding to each 0·1 gramme of pure sodium biurate and keeping in the incubator at blood temperature under frequent agitation for twenty hours. The contents of each flask was then filtered in the incubator through three thicknesses of filter paper. The uric acid was estimated in the measured filtrates by evaporating them down on a water bath, precipitating and titrating by the ordinary method. The second series of experiments were made at another time and with a standard solvent taken from a different stock and were two in number. In these experiments the final titration of the uric acid was made against a $\frac{1}{50}$ normal piperidine solution (instead of $\frac{1}{20}$ normal), the other conditions being exactly the same as described above. In the third set the time of exposure was five hours, the final titration was made against a $\frac{1}{50}$ normal piperidine solution, the other conditions remaining the same. In the fourth set the time of exposure was twenty hours, the volume of standard solvent 100 c.c., the other conditions remaining the same. Four experiments were made simultaneously, which were repeated at another time and with a standard solvent from a different stock with exactly the same result.

TABLE III.—*Showing the Solubility of Sodium Biurate in Standard Solvent.*

Number of set.	Quantity of standard solvent.	Time of exposure.	Uric acid kept in solution.	Calculated as sodium biurate.	Solubility.

[29] Croonian Lectures, 1892, pp. 73–83.

[30] Brit. Med. Jour., April 10th, 1897, p. 905.

[31] In order to make our results comparable to those of Sir William Roberts we prepared the sodium biurate according to his directions. Croonian Lecture, 1892, p. 73.

[32] When smaller quantities of the solvent were taken and the amount dissolved expressed in terms of the amount of solvent required to dissolve unity of the salt a much higher solubility was obtained. This explains itself, if we remember that in making any uric acid estimation an experimental error of 1 mg. or more might easily occur, which, taking, for instance, a solubility of 1 in 100,000 and as quantity of solvent used 25 c.c. is multiplied 4000 times when calculating on the unit.

Digitized by Google

According to the above observations the solubility of sodium biurate for 20 hours varies from 1 in 13,000 to 1 in 116,000 according to the quantity of the standard solvent. In, however, estimating the influence of drugs upon the solubility of sodium biurate in standard solvent we shall take as our standard the solubility of sodium biurate as found when working with the same volume and for the same time as in the experiments in order to make the results with drugs comparable *inter se*.

Influence of certain bases on the solubility of sodium biurate in standard solvent.—Sir William Roberts states that piperazine has no influence whatever on the solvent power of serum (and, *sic*, of standard solvent) on sodium biurate.[33] We may say at once that this does not correspond with our own observations. As will be seen below we find that it does exert an influence in the direction of increasing the solvent power of standard solvent and serum for sodium biurate. In this instance Sir William Roberts attempted to precipitate the sodium biurate dissolved with hydrochloric acid and got no result. It thus appears that he was unable to precipitate by means of hydrochloric acid both the sodium biurate taken up by standard solvent alone (which according to him amounts to 1 in 10,000) and also that taken up by standard solvent plus piperazine. From these experiments he came to the conclusion that piperazine had no influence "whatever" in increasing the solvent power of standard solvent for sodium biurate. The method of precipitation used by Sir William Roberts for his quantitative estimation is, however, inadequate.[34] Smale[35] has recently shown that sodium chloride in the proportion of 0·2 per cent. and upwards exerts a powerful inhibitory influence on the precipitation of uric acid by means of hydrochloric acid. As standard solvent and blood serum both contain about 0·7 per cent. sodium salts, which are by the addition of hydrochloric acid converted into chlorides, it is evident that by hydrochloric acid a complete precipitation of the uric acid in these media is not to be expected. No such objection holds for the precipitation by ammonium chloride.[36] Our comparative results with regard to the influence of the bases in question are best shown by the following table. Five experiments were done with each base and the average of the numbers (which were nearly all identical) was taken.

TABLE IV.—*Showing the Influence of 0·1 per cent. of certain Bases on the Solvent Power of Standard Solvent for Sodium Biurate.*

Quantity of standard solvent.	Quantity of solvent.	Solvent used.	Quantity of sodium biurate dissolved.	Solubility (in round numbers).	Solubility in terms of standard solvent.

Quantities of solids expressed in grammes.

Having considered the solubility of sodium biurate in standard solvent under different conditions we will now proceed to give our results in regard to blood serum.

Solubility of sodium biurate in blood serum.—For the purpose of our experiments we used bullock's serum, of which we obtained from different animals a total quantity of 2½ litres. This quantity formed our common stock, and all the experiments described below were made with it. After filtration through a Berkefeld filter under pressure[37] it was a perfectly transparent pinkish yellow fluid and had the following characteristics: specific gravity (at 15°C.), 1·0269; inorganic substances, 0·84 per cent.; chlorine, 0·30 per cent.; and alkalinity (expressed as NaOH),[38] 0·26 per cent. As will be seen from the table given below (compiled from Bunge's "Physiological Chemistry") the composition of the serum used very nearly approximated the average. The

Graphic Representation of the Results expressed in Table IV. (2 mm. corresponding to 1 mg.).

slight difference between it and human serum justifies us in concluding that the results which we obtained with this serum are applicable to human serum.

TABLE V.—*Showing the Composition of Serum.*

Before applying the method which we described above for the estimation of uric acid in the various fluids we dealt with to blood serum we thought it wise to study the effects of the necessary manipulations on normal serum. An additional reason for making these control experiments consists in the possibility of the serum originally containing some uric acid. From the results of previous workers in this field[39] there seems little doubt that uric acid is normally present in blood but in very minute quantities. As will be seen from our result below we have succeeded in making a quantitative estimation of the uric acid normally present in bullock's serum. For this purpose we took 100 c.c. of the serum and saturated it with ammonium chloride. After filtration and washing with saturated ammonium chloride solution the residue on the filter was well rinsed with hot distilled water into a small glass basin. A slightly turbid liquid was thus obtained to which hydrochloric acid was added in slight excess. On evaporating gently on a water-bath to a small bulk a flocculent white substance appeared, which we regard as a globuline-like body, precipitated by ammonium chloride, further re-dissolved by hydrochloric acid in excess and subsequently re-precipitated by concentration. After two hours' standing in the cold the precipitate was collected on a small filter and carefully freed from hydrochloric acid by washing with water. The completely neutral residue was then rinsed with hot water into a small flask and titrated with $\frac{1}{10}$ normal piperidine. It was found that the piperidine solution had no dissolving influence on the globuline-like body and only 0·08 of the $\frac{1}{10}$ normal piperidine solution corresponding to 0·00029 per cent. of uric acid was required to produce the colour reaction with phenolphtalein (taking regard of the error mentioned on page 200). We are inclined to regard this figure as actually corresponding to the amount of uric acid originally present in the serum. Whether this is the case or not it is obvious that it

[33] Croonian Lectures, 1892, p. 136.

[34] That uric acid cannot be completely precipitated from urine by hydrochloric acid was shown by Salkowsky (Pflüger's Archiv, Band cox., 1872). See also Bunge: Physiologische Chemie, 1894.

Digitized by Google

must be substracted from our future estimations of the amount of uric acid taken up by this serum under varying conditions.

As till quite recently permanganate of potash was the most usual agent against which uric acid was titrated we thought it would be of interest to see what results would be obtained when normal serum was treated as above and finally titrated against permanganate. It was to be expected that a substance such as the globuline body described above would be partially or completely oxidised by a permanganate solution. From this it would result that a larger amount of permanganate solution would be required when uric acid is titrated in the presence of this substance and that the number calculated from that amount would not represent the actual uric acid alone, but the uric acid and other oxidisable substances. It has been confirmed recently by O. Folin[40] that the uric-acid-permanganate coefficient (1 c.c. $\frac{1}{10}$ normal permanganate = 0·003759 uric acid), although purely empirical, is for pure uric acid constant, but is evidently no longer so in the presence of other substances oxidisable by the permanganate. Our results entirely confirmed this *à priori* reasoning. It was found that the residue obtained in exactly the same way as described above from normal serum when titrated with a $\frac{1}{10}$ normal permanganate solution wanted 1·39 c.c. $\frac{1}{10}$ normal. Permanganate solution = 0·0052 per cent. uric acid. The permanganate solution was standardised immediately before use against pure iron and against the same pure uric acid used for controlling the $\frac{1}{10}$ normal piperidine solution. For this pure acid the figures obtained by permanganate and piperidine solution were absolutely the same. It follows from these results that the extraordinary high number calculated from the amount of permanganate required does really correspond to the uric acid present in the serum (which was found to be 0·00029 per cent. with the piperidine method).

We next turned our attention to determining the solubility of sodium biurate in our serum. 200 c.c. of serum were taken and the solubility estimated as described before was found to be 1 in 60,000 (twenty hours).[41]

Influence of certain bases on the solubility of sodium biurate in serum.—The experiments were made in exactly the same way as described above, serum being substituted for standard solvent, and are best shown in the following table.

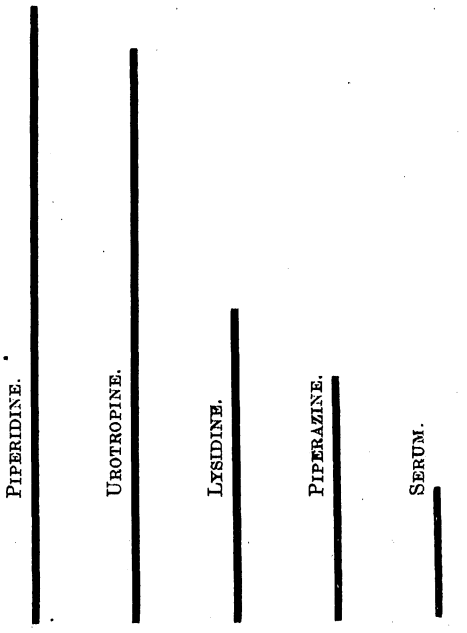

TABLE VI.—*Showing the Influence of certain Bases on the Solubility of Sodium Biurate in Serum.*

Quantity of serum used.	Quantity of solvent.	Solvent used.	Quantity of sodium biurate dissolved.	Solubility (in round numbers).	Solubility in terms of serum.
100 c.c.	0·1 g.	Piperidine.	0·0081 g.	1 in 12,000	4·7

,,	,,	Lysidine.	0·0041 g.	1 in 25,000	2·4
,,	,,	Piperazine.	0·0032 g.	1 in 31,000	1·9
,,	—	—	0·0017 g.	1 in 60,000	1·0

Quantities of solids expressed in grammes.

It will be seen from the above tables that the solvent power of the bases in question is in direct proportion to the solubility of their respective urates in distilled water in the case of urine and urinary sediments, but not so in that of standard solvent and serum. This result we are unable to explain. The physical state of the urates formed, if formed at all, will probably have an influence *per se*. In a complicated fluid like serum the relative strength of the base would also be a potent factor in determining the formation of a urate. A further point to be noted is that the behaviours of standard solvent and serum are by no means identical and that results obtained by the one medium are not applicable to the other and any further experiments which are made in this direction should be made with serum.[42]

Graphic Representation of the Results expressed in Table VI. (10 mm. corresponding to 1 mg.).

CONCLUSIONS.

1. Tartrate of piperidine may be safely given to man in doses of 15 gr. (1 gramme) three times a day or oftener in uric acid gravel and in gout.[43]

2. Taking all the conditions into account this substance is preferable to any other drug up to the present introduced for this purpose, having the additional advantage of being sufficiently cheap to render it within the reach of everyone.

3. Lysidine, piperazine, urotropine all have an influence in increasing the solvent power of serum for sodium biurate and urine for uratic deposit in varying proportions, but to a less extent than piperidine.[44]

In this paper we have made no attempt to examine the *modus operandi* of the so-called uric acid solvents. This subject we shall return to later. Our experiments, so far as they have gone in this direction, have tended to show that all these substances diminish the total amount of uric acid excreted but not the total amount of nitrogen. This fact has led us to the opinion that these substances have a double action in that they, although capable of acting as uric acid solvents, also exert an influence upon metabolism. The close relationship between the constitution of uric acid and xanthin bases, as recently emphasised by the researches of E. Fischer,[45] renders it possible that under the influence of these reducing agents (to which class uric acid solvents mostly belong) uric acid is in the body transformed into xanthin or its immediate allies. This reduction has recently been accomplished in the laboratory with the help of formic acid (chloroform and potassium hydrate).[46]

[40] Zeitschrift für Physiologische Chemie, Band xxiv., p. 224.

[41] This solubility is probably too high, as 200 c.c. is, for reasons explained in a former note (see page 19), too small a quantity of solvent to take. In this connexion we made some estimations and found the solubility apparently considerably increased when small quantities were taken; for instance, the solubility when taking 25 c.c. agreed approximately with that ascribed to it by Dr. Luff (who also worked with 25 c.c.).

[42] This result is of interest, being another instance of the impossibility of obtaining artificially a fluid with the physiological properties of serum.

[43] This substance, at the suggestion of the writers, is now being made on a commercial scale by Messrs. J. Turner and Co., Queensferry, Flintshire.

[44] We should like to express our indebtedness to Dr. D. Ross for the careful and exact manner in which he has helped us in the large number of experiments which were necessary. Some further details of method will probably be published in a thesis upon which he at present is engaged.

NOTES ON A CASE OF

PURULENT CEREBRAL MENINGITIS OF AURAL ORIGIN WITH PECULIAR SYMPTOMS.

BY ADOLPH BRONNER, M.D.,

SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL; LARYNGOLOGIST TO BRADFORD ROYAL INFIRMARY.

THE patient, a lad aged sixteen years, saw me on March 27th, 1898. He had had discharge off and on from both ears since childhood. Six months previously he received a severe blow on the left side of the head and had had pain in the head ever since. A few weeks before I saw him he put a plug of cotton-wool into the left ear and could not remove it. On March 20th he had severe pain in the ear and a swelling appeared behind the ear. Dr. Graham was called in, who removed the cotton-wool and the pain and swelling soon subsided. On the 25th the temperature suddenly rose to 104° F. and on the 26th to 105°. There was a slight rigor. When I saw the patient he seemed rather flushed but was perfectly rational, and with the exception of slight pain in the head and left ear he felt quite well. The pulse, however, was only 54 and the temperature was 100·5°. The patient was put to bed and the pulse and temperature remained about the same till March 30th, when the temperature suddenly rose to 104·5°. The following day it rose to 105°. A soft swelling now appeared behind the left ear and on pressure pus escaped into the external auditory meatus. The left optic disc appeared to be slightly congested. The following day the mastoid cells and attic were opened. The cells were not visibly affected, but the attic contained some caseous matter and débris and its upper wall was rough. The temperature now fell, but on the second day it rose to 105°. The left optic disc became more congested, but there were no signs of papillitis. The pulse varied from 60 to 80. On April 4th the incision behind the ear was prolonged and the cerebral fossa was opened with the chisel from the attic upwards. There was no, or very slight, bulging of the dura mater. Macewen's pus searcher was introduced into the brain, but no pus could be found. The lateral sinus was exposed and found to be normal. The temperature still remained high but gradually fell to 100° on April 13th. It then gradually rose to 102° on the 16th. On the 18th it was again nearly normal and remained so, or subnormal, till death on April 25th. The pulse varied from 60 to 70. On April 7th most peculiar symptoms set in. Slight left facial paralysis was noticed, and aphasia became apparent on the 8th. This increased for 4 days and gradually disappeared. On the 11th the patient had two epileptiform attacks, more marked on the left side of the body. The next day there was well-marked anæsthesia of the left arm up to the elbow, which subsided in two days. On the 18th late at night short epileptiform attacks set in and continued at intervals of from five to ten minutes till the next afternoon.

I am indebted to Dr. Eurich for the following description of the attacks. The jaw moved to the left with a grinding action. The pupils were dilated widely and the eyes were turned to the left, when they twitched in a nystagmus-like manner. Then the frontalis went into clonic contraction on both sides. Subsequently the whole of the left facial region twitched and the eyes were now turned to the right. There was slight laryngeal spasm which ended in sobbing. When these clonic spasms had subsided the patient turned to the right and with an effort raised himself into a sitting position with marked inclination to the right while the right arm was extended out of bed and the left arm was raised. He then sank back into bed; the head was retracted and the back was slightly arched. During the whole fit he was unconscious. He passed fæces and urine involuntarily. All these symptoms seemed to definitely point to pressure on the posterior end of the inferior frontal convolution of the right side. On April 19th a large trephine opening was made about one and a half inches above the right external auditory meatus. There was no pulsation. The dura mater was opened and a large quantity of extremely fœtid pus escaped. The next day the patient became very restless and irritable. He gradually became comatose and died on April 25th.

On post-mortem examination the space between the dura mater and the surface of both sides of the brain was so extensively filled with thick, partly gelatinous, pus that the convolutions were nowhere visible except at the very tip of the occipital lobes. The surface of the brain was rough and irregular. On taking out the brain the pus was found to have involved the base as far back as the apex of the interpeduncular space, including the sheaths of the first to the sixth nerves. All the sinuses appeared to be healthy. There was a small subpial abscess of the size of a marble in communication with the subdural collection of pus and implicating the outer and inner aspects of the left frontal lobe just anterior to the tip of the temporo-sphenoidal lobe.

This case is interesting from many points of view. The fact that the pus extended over both sides of the brain is in itself a not very common occurrence. Some of the symptoms did not point to purulent meningitis and other symptoms which one would have expected were absent. The pulse was slow at the beginning, only from 54 to 60, and varied from 50 to 80 during the course of the illness; only once or twice was it more than 80. The patient was never restless or irritable until a few days before death. Aphasia is a most unusual symptom and was evidently due to a small local abscess in connexion with the meningitis. The patient never vomited, yet sickness is said to be one of the most common symptoms in these cases. The deep and extensive lesion of the cerebral cortex did not cause the numerous and grave symptoms which one would have expected.

Bradford.

A CASE OF PRIMARY SUPPURATION OF BOTH SUPRARENAL GLANDS.

BY W. JANOWSKI, M.D.,

CHIEF OF THE MEDICAL SERVICE IN THE INFANT JESUS HOSPITAL IN WARSAW.

THE patient whose case is now described was a married woman, twenty-five years of age, and was admitted into the hospital under my care on March 4th, 1898. She had passed through small-pox, typhus fever, and diphtheria in childhood. The present symptoms were of three weeks' duration and commenced suddenly with violent shivering fits, which were repeated for several days. She also suffered from severe pain in the back under the right ribs and still had it when she entered the hospital; it was always severe and it spread towards the right side of the posterior and lateral surface of the chest wall and towards the right upper extremity. She was of average size and nutrition and was seven months' pregnant. Her skin was dry, yellowish in colour, and cold, as the fatigue of coming to the hospital had brought on collapse; her conjunctivæ also were faintly yellow. Her pulse was regular, but very weak, and 120 per minute; her respirations were 48 per minute. Her skin was swollen over the spine and seemed to be swollen at the lower part of the right side of the chest wall; it was very painful on the slightest touch both between the ribs and above them, so that she could not lie on her right side. The left lung showed nothing abnormal, but the lower anterior limit of the right lung was on the fourth rib, and the breath sounds were weak. The cardiac dulness was normal. The abdomen was moderately distended. The liver and the spleen could not be felt. The urine was of a very dark-brown colour, suggesting the presence of bile pigment, but no bile pigment, blood, albumin, or sugar could be detected on analysis; it was acid, had a specific gravity of 1022, and did not contain any deposit; the ordinary pigment gave a very dark-coloured reaction with Heller's nitric acid test. The symptoms pointed to paranephritis purulenta dextra; subdiaphragmatic abscess was negatived by an exploratory puncture. On March 5th the patient's state was much the same. During the previous night she had had shivering fits, with a temperature of 39·3° C. (102·8° F.); her pulse was 150 per minute and very weak; the heart-sounds were very feeble. After a consultation with Dr. Krajewski, who agreed in the diagnosis, a long incision was made in the right lumbar region and with some difficulty a collection of fœtid pus amounting to about 100 c.c. (3½ fl. oz.) was discovered

Digitized by Google

around the upper part of the right kidney between the capsule of the kidney and the surrounding fat. The patient's temperature ten hours after the evacuation of the pus was 39·8° C. (103·6° F.). She miscarried on March 6th and died an hour afterwards.

The post-mortem examination, made on March 7th by Professor Przewoski, showed no evidence of disease anywhere except in the suprarenal glands. Both these organs had suppurated and there remained of them only somewhat large capsules full of very offensive yellowish-green pus, in which there floated small necrotic, nearly black remains of adenoid tissue. The left kidney and the left paranephrium were quite normal, the abscess which remained in place of its supra-renal gland being entirely encapsulated. On the right side the capsule was adherent to the lower surface of the liver, but it was found on section that the pus had not penetrated into the tissues of the liver. The capsule of the abscess was not perforated on its lower surface either by the pathological process or by the surgeon during the operation, so that the suppurative infiltration round the anterior surface of the upper half of the right kidney was separated from the suppurated right suprarenal capsule by a membrane 0·5 mm. ($\frac{1}{50}$ in.) thick. The right kidney presented no other pathological process than a slight interstitial nephritis. The uterus was of the size of a child's head; its inner surface was quite healthy. A bacteriological examination of the pus was not made, but the omission was of no consequence as the identification of any particular bacteria could not have explained the formation of the abscesses. The conclusion is therefore inevitable that the case was one of primary suppuration of both suprarenal glands, and in this lies its principal interest, because such instances are very rare. At least, Neusser in his monograph on the diseases of the suprarenal gland remarks that primary unilateral or bilateral abscesses of the suprarenal gland are said to have been seen "in exceptional cases."[1] There is no proof that loss of one suprarenal gland is necessarily fatal provided that a normal one is left, but the destruction of both the suprarenal glands in this case must have caused the patient's death under any circumstances, for life would be impossible in the absence of both suprarenal glands since they have a very important function in connexion with the regulation of the blood-pressure. The extraordinary weakness of the pulse and of the first sound of the heart in this case exceeded anything that I had previously observed and I think that it might have been caused not only by the action of bacterial toxins on the organism but by the localisation of the pathological process in the suprarenal glands. The very dark-brown colour of the urine may have depended not only on an excessive amount of urine pigment but perhaps also on the presence of hæmoporphyrine, &c. Uromelanine has been found to occur in Addison's disease.[2] Perhaps the presence of the three above-mentioned symptoms may in future enable suppuration of the suprarenal glands to be diagnosed before an operation is performed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual general meeting of this society was held on July 15th, Mr. T. G. Alderton, treasurer, being in the chair in the unavoidable absence of the President, Mr. H. P. Potter. The annual report and balance-sheet were presented and adopted. The society has now a membership of 498 and is about to enter much larger and more commodious quarters necessitated by its continued growth. The President's retiring address was read by the senior secretary, Dr. F. J. McCann, and was entitled Some Observations on Old Age. Votes of thanks to the retiring officers of the society were duly passed and the following were elected to fill the offices for the ensuing year, 1898–1899:—President: Dr. S. D. Clippingdale. Vice-presidents: Dr. Lamb, Mr. A. G. Wells, Mr. C. M. Tuke, and Mr. L. A. Bidwell. Council: Mr. F. Lawrance, Mr. Herbert Menzies, Dr. Seymour Taylor, Dr. Elliot, Dr. F. H. Low, Dr. J. Harper, Mr. C. Andrews, Mr. Neville Wood, Dr. F. J. McCann, Mr. F. R. Mallard, Dr. G. P. Shuter, and Mr. F. Savery. Treasurer: Mr. T. Gunton Alderton. Secretaries: Mr. McAdam Eccles and Dr. G. D. Robinson. Librarian: Mr. C. B. Keetley. Editor of Journal: Mr. H. Percy Dunn. Editorial Secretary of Journal: Mr. McAdam Eccles.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF GENU RECURVATUM WITH TALIPES VARUS AND SPINA BIFIDA.

BY JOHN B. O. RICHARDS, L.R.C.P., L.R.C.S. EDIN.

THIS case came under my notice in December, 1897. On Dec. 7th I was called to see a newly-born child as "its legs were not right." The child had been born about 2 hours when I saw her. The nurse in attendance informed me that it was a breech presentation and that there had been no difficulty in delivery. The legs were extended on the thighs at an acute angle, there was no movement whatever at the knee-joint nor could any patella be made out. The joints had the appearance of the flexor surface being in front. The feet were in a condition of extreme varus, the soles facing inwards. Spina bifida existed in the lumbar region, the tumour having a broad, thick base and being covered by membrane only. There was no exudation of spinal fluid and the tumour felt quite tense. Things remained thus till the 10th, when there was escape of spinal fluid and the tumour began to slough. On the 15th there was constant discharge of fluid and sloughing had gone on rapidly. The child was twice convulsed. The fits increased in number till the 19th, when death took place. During the whole period there was no increase in movement at the knee-joints. There was no pain during pregnancy except at the fifth month, when the mother had a fall from a dogcart. She attributes the deformity to this accident. From what I could learn from the nurse there was no excess of amniotic fluid. All the other children, 4 in number, are quite healthy and free from any deformity. The parents refused to allow a post-mortem examination of the joints to be made.

Binbrook, Market Rasen.

A CASE OF SUPRAPUBIC LITHOTOMY.

BY ANTONIUS J. MANASSEH, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a boy, aged four years, was admitted to the Friends Mission Hospital suffering much pain during and after the act of micturition; he frequently passed urine in the day, had incontinence of urine at night, and was noticed to be constantly handling his penis. His prepuce was elongated. Chloroform having been administered and the bladder sounded the presence and size of a calculus was ascertained by this method and by introducing the finger into the rectum. On June 4th suprapubic lithotomy was performed under chloroform and ether, all preliminary antiseptic precautions having been taken. The bladder was injected with 3 oz. of warm boric acid lotion and a metal catheter was left in as a guide to the bladder. No rectal bag was used. An incision 2½ in. in length was made in the abdominal wall close above the pubes and as soon as the bladder was recognised a sharp hook was passed through its muscular coat and two silk stitches were introduced, one on each side of the middle line. The partially distended bladder was opened with a scalpel, the calculus was sought for and removed, and the bladder was then washed out with boric acid lotion and closed with catgut sutures. The abdominal wound was united with interrupted sutures, and a small indiarubber tube was introduced at the lower end of the wound and just beneath the skin but was removed after twelve hours, a soft catheter passed through the urethra being left in the bladder. The patient suffered very little from the after effects of the operation. He vomited once or twice after being removed to the ward, but passed a good night lying on his back. Next morning the soft catheter was removed and the patient was encouraged to pass urine every hour or two, which he gradually did with ease. On the seventh day after the operation the stitches were removed; the wound then looked healthy, primary union occurred, the patient made a speedy recovery, and was discharged on June 21st, 1898, quite well.

The above case illustrates the advantage of suprapubic

Digitized by Google

lithotomy for children. It is not only an easy operation but also free from the risk of wounding important parts. I found the metal catheter a great help to guide me in opening the bladder.

Brumana, Beyrout, Syria.

A CASE OF PELVIC CELLULITIS IN THE MALE.

BY JOHN HUGH REES, M.D. EDIN.,
AND
CHARLES TANFIELD VACHELL, M.D. LOND.

A MAN, aged forty-three years, had been ailing for a fortnight or more, but was first seen by Dr. Rees on Oct. 31st, 1897, and although the symptoms were not characteristic it was thought that the case would prove to be one of mild enteric fever and the patient's diet was prescribed accordingly. The tongue was thickly coated, constipation was persistent and each night there was profuse perspiration; no typhoid spots were noticed. On Nov. 5th the Clinical Research Association reported as follows upon a specimen of the blood: "This serum gives a very marked reaction when in a strength of 50 per cent.; when the serum is used in a strength of 5 per cent. a fairly definite but not complete reaction is obtained within half an hour; after twenty-four hours reaction is still more marked; we should think on the whole that the case is enteric if you are able[1] to eliminate the possibility of a previous attack." On the 20th the temperature, which had been gradually falling since the 12th, became subnormal and continued at or about the normal line until the 27th, when the patient was allowed to get up. At once the temperature rose again until on the 30th it had reached 103° F. Constipation still continued and hard masses of scybala were daily removed by enemata. With rest in bed the temperature quickly declined and became normal on Dec. 13th. On the 19th he got up again; on the next day the temperature again rose and on the 24th was 104°. It was once more normal on Jan. 10th, 1898. On the 16th he was allowed to get up, but on the 17th the temperature again rose and though he was kept in bed on strictly milk diet he was very ill and on the 25th he was seized with severe pain in the lower part of the abdomen, which lasted for 12 hours, the temperature rising to 104°. Constipation was severe, hard scybalous masses being removed with considerable difficulty by means of enemata. The temperature fell to normal on the 31st. On the 29th there was some difficulty in micturition, the flow also stopping suddenly at times; there was tenderness over the bladder region and also much flatulent distention of the abdomen. Scybala were passed daily, being sometimes accompanied with mucus. There appeared on the abdomen spots which had some resemblance to rose spots, but were probably sudamina. On Feb. 6th and 7th the temperature rose to 100° and on the 8th a rectal examination revealed the existence of a large, hard, nodulated, irregular tumour projecting from and filling the recto-vesical pouch. On the 9th Mr. Watson Cheyne saw the patient in consultation. The tumour was examined under chloroform, but no definite diagnosis was arrived at. He was ordered complete rest, aperients, daily enemata, and iodide of potassium, with solid food. On the 19th the swelling had distinctly become smaller and the patient became much more comfortable. The sweats lessened and by the end of the first week in March the tumour had almost disappeared. From this time convalescence was uninterrupted.

[1] There was no history of a previous attack.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the Directors of this society was held on July 13th, Mr. Christopher Heath, Vice-president, being in the chair. Two members were elected and the death of Mr. Henry Lee, Vice-president, was announced. The death of a widow was reported who had been in receipt of grants since January, 1868, and had received in all £893. It was resolved to distribute £1203 10*s.* among the 49 widows and 12 orphans on the books of the society and the 6 recipients from the Copeland Fund. The expenses of the quarter were £44 13*s.* 6*d.* The funded property had been increased by the purchase of £500 Birmingham Corporation Stock.

ST. MARY'S HOSPITAL.

THREE CASES OF EXTENSIVE VENOUS THROMBOSIS ASSOCIATED WITH SEVERE RHEUMATIC CARDITIS; NECROPSIES.

(Under the care of Dr. W. B. CHEADLE and Dr. D. B. LEES.)

FOR the notes of the cases and the pathological and bacteriological investigations we are indebted to Dr. F. John Poynton, medical registrar to the hospital.

CASE 1.—A girl, aged nineteen years, was admitted into St. Mary's Hospital, under the care of Dr. Lees, for shortness of breath and swelling of the arms and legs. In January, 1897, she had suffered from a very severe attack of rheumatic fever for which she had been kept in bed for thirteen weeks and during this time she was reported to have had both pneumonia and peritonitis. The history of this present illness dated from August, 1897, when the patient noticed swelling of the legs and abdomen; in September, however, there was decided improvement. In the first week in October the symptoms again became more urgent and a few days before admission to hospital the left arm suddenly commenced to swell. On admission, on Oct. 19th, her condition was extremely grave. She was very pale and distressed. The conjunctivæ were icteric and there was orthopnœa. The temperature was subnormal and remained so throughout the illness. The legs and thighs were œdematous. The left arm and hand were much swollen and the face was puffy; the right upper extremity pitted on pressure and the upper part of the chest was œdematous. The cardiac condition was that of advanced organic disease. The pulse was 90 and very irregular in force and frequency. Not all the beats of the heart were perceptible at the wrist. The impulse was diffuse and the heart was much and generally dilated. A systolic apical murmur was heard and an accentuated pulmonary second sound. The air entry and percussion note were impaired at both bases posteriorly. The liver was large and tender and the urine contained some albumin and was loaded with urates. For the next few days there was some slight improvement, but at midnight on Oct. 31st the patient became aphasic, the right hand appeared to be weak, and the right leg was kept semi-flexed. Deviation of the head and eyes did not occur. The patient appeared to understand what was said, but she gradually became more and more drowsy. Then followed loss of sphincter control, difficulty in swallowing, coma, and finally death.

Necropsy.—Dr. Poynton made a post-mortem examination twenty-four hours after death. He found that the pericardium was totally adherent, in places firmly and in other parts only feebly so. Both auricular appendices were compressed by the pericardium and round the large vessels the pericardial and mediastinal tissues were œdematous. The heart weighed 16 oz. and the cavities were dilated, especially that of the right ventricle. The mitral orifice was slightly narrowed by old rheumatic endocarditis, but the valve deformity was quite moderate. The aortic valve was incompetent from previous rheumatic endocarditis. The tricuspid valve was incompetent but there were no rheumatic changes in this valve. The pulmonary valve was natural. The right auricle was empty. The left ventricle was 1¼ in. thick. The muscle was firm and of good colour. Both lungs were adherent to the chest wall. Both internal jugular veins were like firm cords and contained adherent clot throughout their entire extent. The lower end of the left internal jugular was white and narrowed and very firm. Both venæ innominatæ contained adherent clot and the left one could hardly be recognised among the œdematous tissue of the mediastinum. The upper part of the superior vena cava contained clot which was firmly adherent to one side of the

Digitized by Google

vein wall but did not occlude the entire lumen or project into the auricle. There was no clot in the inferior vena cava. The brain was generally softened but no local change or change in any particular vessels was found. The liver showed advanced nutmeg changes due to tricuspid incompetence. The kidneys were indurated from chronic venous congestion.

CASE 2.—A young woman, aged twenty-one years, was admitted to the hospital under the care of Dr. Cheadle on Feb. 9th, 1898. When a child she had suffered from an attack of scarlet fever which was followed shortly afterwards by an attack of rheumatic fever. Two years ago she suffered from a second attack of rheumatic fever. This present illness began gradually with weakness, increasing dyspnœa, and œdema of the face and legs. On admission to hospital the patient was very ill, the face was puffy, and she was very anæmic. The temperature was 101°F., the pulse averaged 128 and the respirations 28. The legs pitted on pressure. The pulse was regular and of low tension; the heart was dilated. On auscultation a loud systolic murmur was heard all over the front and back of the chest; the impulse was diffuse and a systolic thrill could be felt. Bronchitic sounds were heard over both lungs. Neither the liver nor the spleen could be felt below the costal arch. The urine contained albumin, blood and some tube casts, and the specific gravity was 1020. During the next week there was marked dilatation of the heart, with irregular pyrexia, free sweating, and decided increase in the œdema and dyspnœa. On Feb. 18th the liver and spleen could both be felt below the costal margin. The urine was scanty and contained albumin and blood, but no more casts were found in spite of repeated and careful search. One special feature of this case was a frequent and harassing cough, for which there was no apparent explanation. On the 21st there was complaint of pain in the wrists and left forearm, the face was more puffy and the conjunctivæ were icteric; the pain in the forearm was localised to the inner side over the region of the flexor carpi ulnaris and palmaris longus; this area was very tender, but there was no local redness. During the next week there was distinct improvement and the heart became smaller, but this was not maintained and in the first fortnight of March the pyrexia, which had been persistent, became more marked and more irregular. The pulse was now irregular and there was orthopnœa, with attacks of severe dyspnœa. On March 17th sudden pain was felt in the left loin and more blood appeared in the urine. The left lung was dull at the base and over a considerable area tubular breathing was heard. The face, which had become almost free from œdema, now again became puffy, especially upon the left side. On the 19th some casts were again found in the urine together with blood, the heart was very dilated, and the patient was moribund. She died on March 20th.

Necropsy.—A post-mortem examination was made by Dr. Poynton on March 21st. The pericardium contained a slight excess of clear fluid, but there was no definite pericarditis. The heart weighed 14 oz. All the cavities were much dilated; in addition there was distinct hypertrophy of both ventricles and of the left auricle. The muscle was pale. The mitral orifice was slightly larger than natural, as also was the tricuspid. There were numerous exuberant granulations on the mitral valve and a portion of the anterior cusp was free, the chordæ tendineæ attaching it to the papillary muscle having ulcerated and given way. Vegetations had also spread along the anterior wall of the left auricle upon the inner surface. On the wall of the left ventricle below the mitral valve were a few isolated vegetations. The tricuspid, aortic, and pulmonary valves were not affected. The lower lobe of the left lung was solid with pneumonic change; the right lower lobe was extremely congested but did not sink in water. The spleen weighed 8 oz. and there were two infarcts within it, one of which was quite recent. The liver weighed 44 oz. and was fatty. Each kidney weighed 6 oz. and contained one infarct; the capsule of each was thickened but not adherent; the cortex was pale. In the left internal jugular vein was a clot extending from the junction with the left subclavian to the angle of the jaw. This was pale and adherent to the wall, especially in the lower part, where the vein was cord-like. The innominate veins and right jugular were not thrombosed nor were the inferior vena cava and its larger tributaries. The brain appeared to be quite natural.

Microscopical examination.—Dr. Poynton is indebted to Mr. Brincker, post-mortem assistant at the time, for much assistance with the microscopic work. The pericardium showed in the visceral layer some early inflammation. The heart muscle had lost striation considerably and most of the fibres showed pigmented perinuclear granules. The mitral valve was much affected by inflammation, but we were unable to demonstrate micro-organisms in the granulations. Sections of the left internal jugular vein showed an organising thrombus, but micro-organisms could not be demonstrated in the vein wall, which was not distinctly thickened. No organisms were found in the clot. Sections of the right internal jugular, which was not thrombosed, appeared to be natural. The left lung was pneumonic and numerous diplococci were demonstrated by Gram's method. The kidneys showed no sign of interstitial inflammation from any old-standing nephritis. In the neighbourhood of the infarcts there were hæmorrhages in the substance, and the renal epithelium showed much cloudy swelling, but otherwise nothing remarkable was observed.

CASE 3.—A girl, aged nine years, was admitted to the hospital under the care of Dr. Cheadle on Feb. 19th, 1898, for swelling of the body and limbs and collapse. Two years previously she had suffered from an attack of scarlet fever, since which time the heart had been affected. There was a marked rheumatic history upon the father's side. The mother unfortunately was addicted to alcoholism, so that it was not possible to obtain a careful description of the onset of the present illness. The child had been ailing for three weeks with pain in the chest and cough, and during the last week dropsy was noticed. On admission to hospital the patient was very pale and the face was œdematous, the expression being distressed. There were slight cyanosis and orthopnœa. The temperature was 97·4° F., the pulse averaged 100, and the respirations 30. The fingers were clubbed, the lower extremities were œdematous, and the front of the chest pitted on pressure. The abdomen contained some fluid. The pulse was irregular, weak and small. The heart was much enlarged; the left limit was four finger-breadths external to the left nipple and the right limit was three finger-breadths external to the right margin of the sternum. There were marked epigastric pulsation, præcordial bulging, and a systolic and diastolic thrill. At the apex a systolic murmur was heard and over the aortic cartilage systolic and diastolic murmurs were audible. There was also a doubtful pericardial scratching sound heard to the left of the sternum. The air entry was impaired over the bases of both lungs and there were scattered rhonchi and sibili over both the front and the back of the chest. The appetite was good, though the tongue was furred. The urine was acid, the specific gravity being 1025; it contained albumin and blood, but no casts. The liver was enlarged and pulsating. The child slept with her face turned towards the pillow. After admission to hospital the œdema gradually subsided and the blood in the urine disappeared. Steady improvement was maintained until March 10th, when pleural friction was heard in the left axilla and there was distinct dulness on percussion at the left base. The urine contained a trace of blood, but there was not any rise of temperature. After this outbreak there was again improvement, the œdema disappeared, the liver became smaller, and the signs in the left pleural cavity cleared up. On April 10th there was once more pain in the left side and also dulness at both bases. The axillary glands were noticed to be enlarged. The heart was more dilated and the action was feebler; the liver also had increased in size. On the 13th the left side of the face became swollen and on the 16th there was marked œdema of the right side of the neck, the face was purple, and the eyelids and lips were swollen. Both sides of the neck were tense and tender on the least pressure. Movement of the neck was painful. The temperature was subnormal; there was no swelling of the legs or ascites. Dr. Cheadle saw the child and diagnosed thrombosis of the internal jugular veins. On the 17th the right arm began to swell. Mr. Willcox, a medical clerk at St. Mary's Hospital, kindly took a photograph of the patient, of which Fig. 1 is a reproduction. Mr. A. L. Saunders, demonstrator of anatomy at St. Mary's Hospital, subsequently made a sketch (Fig. 2) from the dissection of the thrombosed veins. Shortly after the right arm had become swollen the left arm began to swell. The chest was œdematous. The child was very apathetic and took food badly. On the 18th she was very drowsy and apathetic and the face was cyanosed. At midday there was sudden dyspnœa and two attacks of great restlessness occurred. The extremities became cold and the pulse at the wrist was imperceptible;

Digitized by Google

there was much suffering. On the 19th the œdema of the right arm was extreme and there was tenderness on pressure, but the face was less swollen. The respiration was slow and sighing. On the 20th two firm cords were felt in

the lower part of the neck. The legs and feet were a little swollen. The area of cardiac dulness was now enormous and there was loud general pericardial friction. Sharp crepitations were heard over both lungs. The urine was scanty; it

contained a trace of albumin and no blood. Food was refused. Death took place on the 21st.

Necropsy.—A post-mortem examination was performed by Dr. Poynton on Feb. 22nd. There was great difficulty in obtaining permission and the cranial cavity was not opened. The pericardium contained between 4½ oz. and 5 oz. of turbid fluid and the surfaces were coated with recent lymph. All the cavities of the heart were dilated. Both ventricles were hypertrophied, the right proportionately more than the left. The mitral orifice was incompetent, the valve segments and chordæ tendineæ were thickened, and in addition along the cusps were some recent vegetations. The tricuspid orifice was incompetent and along the cusps were recent vegetations. The auricles were dilated, but the right auricle was empty. The aortic valves were thickened and incompetent and beaded with recent vegetations. The pulmonary valves were natural. The following veins were thrombosed: the right innominate, subclavian, axillary, internal and external jugulars—the last only in the lower part of its course; the left internal jugular, external jugular, inferior thyroid, axillary, subclavian and innominate. In its upper two-thirds the superior vena cava was thrombosed. Looking into it from the auricle a pale, soft clot could be seen, not adherent, blocking completely the lumen of the vessel; higher up the clot was quite firm. Both internal jugulars felt like firm cords in their lower part and were white and small, whereas in the upper part they were bulged with soft clot. The left innominate was small and white and only admitted a small probe. The veins were more adherent to the surrounding tissues than usual. Fig. 2 represents the appearance found post mortem. Though more extensive it is quite comparable to the condition found in Case 1, but there was no pericardial adhesion or obliteration of auricular appendices as in the latter. The inferior vena cava and its tributaries were natural. Unfortunately, whether as in the first case the brain was œdematous could not be ascertained nor whether the lateral sinuses were thrombosed. It is, however, certain that the clotting did not begin in these sinuses, for the further the distance from them the older was the thrombosis in the jugular veins. Nodules were present on the dorsum of the right foot and in the scalp. The remaining organs showed the usual secondary changes from advanced morbus cordis. There was no evidence of infarction.

Microscopical and bacteriological examination by Dr. POYNTON.—Cultivations from the pericardial fluid, lymph, and blood-clot were negative, as also were films made from the pericardial fluid and blood-clot. The conditions of the heart wall and pericardium are of interest because they represented the condition of a very acute rheumatic carditis. As regards the pericardium the vessels in the subserous areolar tissue of the visceral layer were extremely congested and the areolar tissue surrounding them was much swollen and hyaline in appearance. The superficial connective tissue layer contained numerous inflammatory cells, and, finally, there was an adherent layer of lymph, the serous epithelium having disappeared. The same process could be traced throughout the heart wall along the course of the vessels; there were the same swelling of the connective tissue supporting them and the same inflammatory cell exudation—this could be traced between the muscle fasciculi—and the capillaries between the fibres were dilated. Immediately beneath the pericardium the process was quite distinct and there was loss of striation, but no gross change was apparent in these superficial layers as compared with the deeper. The muscle fibres, with their nutrition altered thus and supplied by blood probably toxic with the rheumatic poison, must necessarily have suffered throughout the heart wall. Sections taken through a papillary muscle, with its chordæ and a part of the mitral valve, showed very markedly this interstitial inflammation. The soft clot in the superior vena cava was hardened and sections were cut, but no organisms were discovered. A series of sections were made from the right brachial vein to the axillary, from a region not thrombosed to a region definitely so. Sections of the vein showed the clot gradually permeated by spindle and round cells, with formation of a network, the adhesion of the clot to the vein wall, first at one place, then at several, by means of branches spreading in from the intima, and finally the formation of canals lined with spindle cells. In these sections the vein wall was not noticeably thickened, but as the thrombus became more firmly attached there was evidence of early phlebo-sclerosis. Doubtless the lowest portion of the internal jugulars would have shown this process more markedly. No micro-organisms were found either in the clot or vein wall. A section from the left brachial showed a small adherent

Digitized by Google

thrombus at one point, slightly diminishing the lumen of the vessel.

Remarks by Dr. POYNTON.—Owing to the detail in the description of the cases given above it seems advisable to briefly review them, as they are unquestionably of different value. Case 1 is incomplete—clinically because the patient was such a short time under observation and pathologically because, ignorant of the rarity of the condition, which fact was first pointed out to me by Dr. Cheadle, I made no minute observations. Case 2 is an unusual one, resembling very closely malignant endocarditis. It is included with the other two because no micro-organisms were found upon the valves and more especially because, the etiology of acute rheumatism being still obscure, the exact place which malignant endocarditis must take in relation to it must still be uncertain. Having pointed out the gradual onset, the continued pyrexia, the sweating, infarction, and ulceration of the chordæ tendineæ, it is left open to challenge as to whether or not the condition is comparable to that of the other two cases. Case 3 is by far the most complete, for the diagnosis was made some days before death and the symptoms were accordingly studied with more precision. The remarkable similarity in the distribution of the thrombosis in Cases 1 and 3 has been alluded to earlier in this article.

In a comprehensive paper by Gatay on *La Phlébite Rheumatismale*[1] two views are put forward in explanation of the thrombosis. One is that of Schmidt, who considered the thrombosis primary, and the other is that of Letulle and Gatay, who considered a rheumatic phlebitis to be the first event. Confining my attention solely to the cases mentioned above, it seems to me impossible, so long as the exact etiology of rheumatic fever is obscure, to decide which process was the initial one. It is certain that the blood-current was feeble, for the heart muscle was distinctly affected in two cases, and in all there was much organic disease with tricuspid incompetence; the blood was altered, for there was profound anæmia, and both these conditions predispose to thrombosis. On the other hand, the veins most affected were veins in which the circulation was aided by gravity, especially as there was orthopnœa, though where the thrombosis was most advanced the vertical current in the jugulars meets a more or less cross current in the subclavians. Again, in two cases there was active carditis, which suggests the possibility of phlebitis, and in one case there was periphlebitis. Changes in the vein wall would rapidly follow a primary thrombosis and apart from the periphlebitis the changes found were not in favour of a primary phlebitis. That such poisons as snake venom produce a "ferment thrombosis" is well known and it is possible, on the other hand, that a weakened circulation may intensify the effect of the rheumatic poison and thus cause inflammation in structures such as the veins, which are more rarely affected. So much, in fact, depends upon the exact nature of the rheumatic process that in such complicated cases as these are it seems hazardous to dogmatise.

The duration of the thrombosis is a point which has considerable practical interest. The changes in the axillary vein described above pointed to a duration of at least eight days and the condition in the jugulars was of considerably longer standing. Now in both the cases under observation for some weeks there was varying œdema of the face, noted from the time of admission, which is not common in cardiac disease. Again, sections of one vein showed in some places clot adherent in one place only, whilst elsewhere the lumen was free. These facts point to the possibility of a gradual thrombosis having occurred during a period of weeks, with exacerbations when the disease flared up, and at last the final standstill. Œdema of the face, which is more commonly observed in the advanced morbus cordis of children, may in some of the cases, perhaps, depend upon the occurrence of a partial thrombosis of this kind.

The diagnosis may not be quite easy. In Case 3 Dr. Cheadle pointed out the close resemblance in the appearance of the neck to severe parotitis and to angina from severe throat affections. Again, when there are blood and albumin in the urine the œdema and pallor of the face are very suggestive of Bright's disease. The distinctive features are the local appearance and spread of the œdema, the marked tenderness, and the extreme swelling and pain on moving the head in the severe cases. The feeling of the firm cords in the neck is convincing, but not an easy observation because of the danger of any but the lightest manipulation, and also the tenderness and the rigidity of the inner heads of the sterno-mastoids. Mental apathy is a remarkable symptom. The prognosis of these cases, apart from the thromboses, is exceedingly grave, and that they introduce an additional element is shown by the occurrence of aphasia and a gradual coma in the first case and sudden dyspnœa and pulselessness in the second. The treatment must necessarily be considered from the view of the general condition present, and great care in moving the patient is necessary where there is this additional complication.

Thrombosis in rheumatism is quite one of the rarer features of this disease. Dr. Archibald Garrod in his treatise on Rheumatism makes a very definite allusion to it and quotes the researches of Schmidt and Letulle upon the condition. Dr. Cheadle mentioned to me other cases he had met with. Gatay in his paper in 1896 describes two cases with necropsies; one (Macaigne and Laurens's case) showed small-celled infiltration of each coat of the vein and desquamation of the endothelium followed by an inflammatory change in the vessel wall. Bacteriological results were negative. In this case thrombus was found in the brachial, axillary, and subclavian veins. Renouard noted difficulty in turning the neck in one case. Gatay states that it can attack the veins of the neck, but it is exceptional for it to start in the jugulars. One case is quoted where a thrombus was found in the external jugular only. Macaigne and Laurens noted in their case the heavy mental state. Petechiæ, erythemata, and fever are pointed out as occurring simultaneously with the thrombosis and the veins may be arborescent in the neighbourhood. It would appear from the literature on the subject that the veins of the extremities, especially the lower extremities, are most frequently affected. Two of the cases recorded above certainly appear to be quite remarkable both in their similarity and the great extent of the thrombosis.

In conclusion, I must thank Dr. Cheadle and Dr. Lees for most kindly allowing me free use of the clinical notes. I must also thank Mr. Plimmer, bacteriologist to the hospital, for suggestions and advice in the microscopic work; Mr. A. L. Saunders for the sketch of the thrombosed veins; Mr. Willcox for the photograph of one of the patients; and Mr. Brincker for help with the microscopy in one of the cases.

Reviews and Notices of Books.

Sir Benjamin Collins Brodie. By TIMOTHY HOLMES, M.A. Cantab., F.R.C.S. Eng. Masters of Medicine Series. 8vo. London: T. Fisher Unwin. 1898. 3*s.* 6*d.*

THE newest volume of the Masters of Medicine Series from the pen of Mr. Holmes describes in a clear, pleasant, and scholarly book Sir Benjamin Collins Brodie's career of unbroken success. Brodie was of ancient Scotch lineage, but his grandfather came south in the early half of the eighteenth century, having been involved, probably, in Jacobite plottings, Brodie's father, Peter, was a *protégé* of the first Lord Holland, in accordance with the terms of whose will he became rector of Winterslow in Wiltshire. Benjamin, the subject of Mr. Holmes's biography, was the third son of the rector of Winterslow by his marriage with Sarah, the daughter of Benjamin Collins, the Salisbury printer and banker, who published and was part proprietor of the copyright of the "Vicar of Wakefield." He was born in 1784 and brought up at home very strictly, receiving the sound classical education which would be expected from the character of his forbears. In 1801 he came to London to Abernethy's School of Anatomy, and in 1803 he joined the St. George's Hospital Medical School in the character of Sir Everard Home's pupil. His choice of profession seems to have been dictated by family reasons and not at all by any personal proclivity. Dr. Denman—father of the Lord Chief Justice—was his uncle by marriage; Dr. Baillie, nephew of the great John Hunter, and Sir Richard Croft, the leading accoucheur of the day, had married his cousins; while Sir Everard Home as Hunter's brother-in-law was a connexion. At St. George's

Digitized by Google

Hospital Brodie worked hard at literature and physiology as well as anatomy and surgery, and kept carefully written notes of the cases under his staff-surgeon's charge—not at that time a usual proceeding. In 1805 he became house-surgeon. This post he held for six months, resigning it to lecture in anatomy at the Great Windmill-street School. Three years later, when only twenty-five years of age, he was elected assistant surgeon to St. George's Hospital under the style of "Assistant to Sir Everard Home," for in those days there were no assistant surgeons, or assistant physicians so-called, and the present out-patient difficulty was unknown. From this time he went on from strength to strength. In 1809 he set up in private practice with almost immediate success. In 1810 he was elected a Fellow of the Royal Society for his practical work on embryology, and in 1811 he received the Copley Medal of the Society, being the youngest Fellow who had ever received the award. In 1812 he began to work systematically at the great topic with which his name will always be associated as a surgical writer—the diseases of joints. Mr. Holmes considers that it was Brodie's "chief achievement as a surgeon that he threw so clear a light on that most important, because most common, class of diseases"; and that in this way most notably his "surgical labours tended to benefit humanity and to shed a light on the true interests of life (*inlustrans commoda vitæ*)." Before Brodie's work the whole subject of the diseases of joints was treated in an illogical manner; curable diseases were mixed in the surgeon's mind with incurable, and no clear line was drawn between the conditions dependent upon real pathological changes and those which are generally styled hysterical. It was into this sort of chaos that Brodie introduced order. We do not attempt to trace Brodie's career step by step, because we hope that all our readers will go to Mr. Holmes's book for the details of the very interesting story of the life of this master of medicine—Lord Lister's great predecessor in the double character of eminent surgeon and President of the Royal Society. No great surgeon, save only, perhaps, Sir Astley Cooper, has ever bulked so largely in the public eye as Sir Benjamin Brodie and in reading Mr. Holmes's book we can see the reason for this. Brodie was an eminently sane and safe man, who had reached his conspicuous place in the world by methods which were not only creditable to his genius but comprehensible to the public. His science was the straightforward exemplification of the best surgical work of his day. While ready to accept developments and while showing that he was capable of initiating them, he remained respectful to precedent. There was nothing mystical about him and nothing slap-dash. His industry was undoubted and his scholarship respectable. To the medical profession he was a very tower of strength, so high did he stand in the opinion of the outside world as the great surgeon, the President of the Royal Society, the friend of princes, the gentleman by birth and manners but no less the self-made man by work.

"The only physicians," says Mr. Holmes concerning Brodie's Presidency of the Royal Society, "who have been thought worthy of this great distinction were Sir Hans Sloane and Sir John Pringle, besides Wollaston, who, however, threw up both the presidency and the profession in disgust when he was rejected as a candidate for the office of physician to St. George's Hospital. The great man who now fills the chair of the Royal Society is the second surgeon who has filled that office, and the one who has probably succeeded more than any other person who has yet lived in applying science directly to the saving of human life, as Brodie may be said to have been the one who succeeded more than all his predecessors in connecting the pursuit of surgery with the cultivation of science in general. It was John Hunter, indeed, who first established the connexion between surgery and the science of physiology and who then became, as his monument in Westminster Abbey justly styles him, 'The Founder of Scientific Surgery'; but it was Brodie's peculiar glory, his main title to posthumous fame, to have carried this connexion further and to have shown how much the practice of surgery may gain from the possession by its professor of a competent acquaintance with physical science in general and how much he may thereby raise the whole profession in the estimation of the public."

This passage is an excellent summary of Brodie's claims as a man of science over and above his claims as a pure surgeon.

It has been pleasant to us, as it will be to all medical men, to read this story of steady, well-earned success, and Mr. Holmes's style will add much to the enjoyment. The author's range of reading is displayed in his comments; while the practical wisdom of his views on such topics as, for example, the over-examination of students, the proper attitude of the medical profession towards quackery, and the due scope of the work of the General Medical Council cannot be gainsaid. Yet there is no display of learning and no dragging in by the heels of contentious topics. Mr. Holmes never forgets that he is writing a Life of Brodie; but again and again, and unconsciously, he proves that he is the man to give us a proper estimate of his subject. Brodie was more than a surgeon and Mr. Holmes is more than a biographer.

Guide to the Examination and Treatment of Sick Children. By JOHN THOMSON, M.D., F.R.C.P. Edin., Extra Physician to the Royal Hospital for Sick Children, Edinburgh, &c. Pp. 336, with 52 Illustrations. Edinburgh: William F. Clay. 1898. Price 9*s*.

DR. THOMSON'S book is a notable addition to the literature of the diseases of children. It is written entirely from a clinical standpoint, concentrating the reader's attention on the sick child and on the various changes which are produced by different forms of disease. There is no attempt at a systematic description of any maladies, a general knowledge of clinical medicine being assumed. But Dr. Thomson has brought out with great skill the salient characteristic features which would be observed at the bedside of a child suffering from diseases of the respiratory organs, for example, as distinguished from those which would be present in an adult. In a similar way he has drawn attention to the peculiarities of children in their susceptibility to drugs or other therapeutical weapons. The task which Dr. Thomson set himself was an extremely difficult one, and we may preface this notice by saying that he has accomplished it with rare success.

The book commences with an excellent summary of the leading facts in connexion with the growth and development of the child, including the acquisition of speech, followed by an account of the affections which are associated with the epochs of development. With regard to the influence of teething Dr. Thomson steers a middle course. This influence, which older writers made responsible for most infantile disorders, has, according to him, been enormously exaggerated. "At the same time it is equally certain that teething, like menstruation, pregnancy, and other mental states, is often accompanied by marked symptoms both local and reflex, and like them may produce temporarily a tendency to disease which is not present at other times." There is a chapter on the physiognomy of disease which is a model of close observation and is illustrated with some very characteristic photographs showing the facies associated with acute diarrhœa, nephritis, adenoids, and congenital syphilis. The examination of the various regions of the body is then systematically considered and the significance of the signs and symptoms is given in a clear but not too dogmatic style. Dr. Thomson does not hold the view that the presence of craniotabes is necessarily indicative of congenital syphilis, but he admits that the most severe degrees are rarely found.

Digitized by Google

except in children who are syphilitic as well as rickety. The section on Heart Disease, both congenital and acquired, will well repay perusal. Dr. Cheadle's teaching has been followed and the striking differences in the clinical picture presented by cases of cardiac disease in childhood and adult life is very well brought out. The section on the Indications of Mental Defect is very useful, as Dr. Thomson describes the appearances met with in quite young children, while the text-books on the subject only deal with children in institutions who are considerably older. There are some particularly instructive photographs illustrating the appearance of infants suffering from the Mongolian form of idiocy which are the only ones which we have seen of this early stage, and there are also characteristic photographs of infant cretins. There is a very useful chapter on Infant Feeding. Dr. Thomson has, like most authorities, a very poor opinion of the various patent "foods." He insists that till the tenth month, if all goes well, the breast-milk should form the main part of the child's food. In cases where breast feeding is impossible full directions are given for modifying cows' milk in order to make it suitable for the child's use under different circumstances and an adequate account of the most convenient methods for sterilising the milk in the house is given. There is an important section in which a short description is given of the Disorders due to Improper Feeding and their Treatment, including a well illustrated section on Rickets and Scurvy. Dr. Thomson agrees with Dr. Barlow that infantile scurvy is due almost always to feeding on patent foods, condensed milk, or milk which has been subjected to prolonged sterilisation. There is an account of the dosage and of the employment of different drugs in the case of young children. Several appendices which the practitioner will find useful are given—viz., a synopsis of the period of incubation and of the duration of infection in infectious diseases, a formulary of prescriptions and of recipes for the preparation of foods, and directions for the rubbing, &c., of paralysed limbs. The value of the book for reference is increased by a very full index.

It will be seen, therefore, that Dr. Thomson's book does not go over the ground covered by the ordinary text-books but is supplementary to them. It is full of information which every practitioner ought to possess on subjects which are usually found scattered through books, but which he here for the first time finds collected in one volume, and we can strongly recommend it both to students and practitioners. Dr. Thomson is well known to the profession by his careful writings on the subject and the present volume will certainly add to his reputation as an observer and as a teacher.

Cataphoresis or Electric Medicamental Diffusion as applied in Medicine, Surgery, and Dentistry. By WILLIAM JAMES MORTON, M.D. With 76 Figures. New York: American Technical Book Co. 1898. Pp. 267.

THE action of electrical currents in promoting the passage of salts through animal membranes has long been established and some of the applications of this property to medical practice have also been long known. Dr. Morton confers a benefit upon the medical profession by giving us a book in which the subject is treated in a practical way, with descriptions of the apparatus, the methods and the formulæ which the author has found to be the best. He tells us that "since 1853 the peculiar property of the electric current of driving medicines into living tissue has hung suspended in the air, so to speak, and has never been brought down to practical bearings in spite of continuous and ingenious effort on the part of numerous individual experimenters." This book seems to meet the requirements of the case very well for it gives a properly worked-out sketch of the history of cataphoresis and of the work done by previous investigators, and then goes at length into the practical details of the modern modes of application, to the working out of which Dr. Morton has largely contributed. The account of the experiments of Sir B. W. Richardson with solutions of aconite and chloroform for producing local anæsthesia and of the opposition which his work aroused are very interesting. We are told that Richardson was attacked so fiercely that he felt obliged to abandon his experiments.

The production of local anæsthesia by cocaine introduced electrically through the unbroken skin is in some ways the more immediately interesting part of cataphoresis and a considerable part of the book is devoted to its applications in surgery and in dentistry. The easy production of a small area of anæsthesia offers peculiar advantages in dental work. In the United States the use of cataphoresis by dentists seems to be gaining ground and in this country also inquiries are being made into its value by dental surgeons. Dr. Morton states quite confidently that his methods can produce complete local anæsthesia in from four to eight minutes. The subject quite deserves to be taken up by those who are interested in it. The volume is handsomely bound and is printed on thick paper in good type and is an important addition to the literature of medical electricity.

Twentieth Century Practice of Medicine. Edited by T. L. STEDMAN, M.D. Vol. XIII. With 13 Figures. Sampson Low, Marston, and Co. 1898. Pp. 621.

THE present volume begins the Infectious Diseases, but almost two-thirds of it are devoted to introductory articles and the great bulk of the infectious diseases are left over for treatment elsewhere. The first of the four general articles is on Ptomaines, Toxins, and Leucomaines and has been wisely entrusted to Professor V. C. Vaughan, who wrote the kindred article on Food Poisoning in Loomis and Thomson's "Contemporary System of Practical Medicine." After some preliminary remarks, a list of the known ptomaines is given and a brief statement is added as to the conditions under which they are formed and their more important properties. In a clear manner the steps by which specific bacterial toxins have been shown not to be albuminous are gone through or detailed. As the poisons of saprophytic bacteria are generally introduced into the body with food, they are discussed under the heading of Food Poisoning or Bromatotoxismus. Professor Vaughan has, with the help of his classical colleague, Professor F. W. Kelsey, invented a number of new and somewhat lengthy terms for the various kinds of food poisoning: mytilotoxismus (mussel), ichthyotoxismus (fish), kreototoxismus (meat), sitotoxismus (vegetable food), and so forth. The necessity of these terms is not very apparent and it is probable that the simple English terms will be sufficient and will survive. The matter of these sections is, however, in every way most excellent and thoroughly reliable. An account of the poisons of the specific infectious diseases is then given and the article closes with a good summary of our present knowledge on leucomaines.

Professor H. C. Ernst of Harvard contributes an exhaustive article on Infection and Immunity in which the methods and paths of entrance of infection are first considered; some interesting examples are given of the spread of infection by flies and by books. After stating and considering the theories which have been put forward to explain the nature and manner of production of immunity the author proceeds in considerable detail to describe the serum treatment. Our knowledge on the general properties of blood serum, such as its bactericidal, attenuating, antitoxic, immunising powers, are first sketched. The effect of serum treatment on the experimental diseases is then described and its practical uses in human diseases and in snake-bites are epitomised. In conclusion, there is an account of the theory of the protective action of serums.

Water-borne diseases are divided by the late Mr. Ernest Hart and Dr. Solomon Smith into two main groups according as the contaminating substance is living or not. After a brief reference to the first class of diseases a full discussion on the spread of the bacterial diseases, typhoid fever and cholera, is entered upon. In these sections the valuable work done by the late editor of the *British Medical Journal* is fully made use of. In like manner Dr. Dawson Williams brings the results obtained from the elaborate report of the Clinical Society of London into his article on Incubation and Infectiousness in the Acute Specific Diseases, and thus provides a valuable and authoritative article.

After these general and introductory articles, which occupy considerably more than half the volume, we come to the consideration of the individual specific fevers. The first, on Small-pox, is an exhaustive monograph by Dr. J. W. Moore of Dublin. It is well illustrated by charts, cases, and photographs and is evidently the outcome of very extensive research and thoughtful study. From personal experience Dr. Moore speaks well of the red light method of treatment.

Vaccina, which is evidently a mistake for vaccinia, and is probably due to the French term for cow-pox being *vaccine* is the title of Professor Brouardel's (of Paris) article on cow-pox and vaccination. After considerable discussion he sums up in favour of the non-identity of variola and vaccinia. A full description of the normal vaccinal eruption is followed by an account of its anomalies and of the secondary infections which may occur.

The last article in this volume is on Mumps and is contributed by Dr. Salis Comby of Paris, the editor of the *Archives de Médecine des Enfants*. It enters into great detail and should form an admirable source of reference on the subject.

The admirable articles in this instalment fully maintain the international character of the "Twentieth Century Practice of Medicine."

Tablets of Anatomy: Dissectional and Scientific. By THOMAS COOKE, F.R.C.S.Eng., B.A., B.Sc., M.D. Paris, Surgeon to Out-patients, Westminster Hospital, and Lecturer at the School of Anatomy, Physiology, and Surgery; and F. G. HAMILTON COOKE. In Three Parts. Part I.: The Bones. With 230 Illustrations. Pp. 188. Price 7*s.* 6*d.* net. Part II.: Limbs, Abdomen, Pelvis. With 254 Illustrations. Pp. 376. Price 10*s.* 6*d.* Part III.: Head and Neck, Thorax, Brain. With 286 Illustrations. Pp. 420. Price 10*s.* 6*d.* 4to. London: Longmans, Green, and Co. 1898.

MR. COOKE'S Tablets are so well known and we have on so many previous occasions spoken in favour of them that it is almost superfluous to say anything in their praise now. The author has been for many years a most earnest advocate of the importance of careful dissecting for a good knowledge of anatomy, and therefore it goes without saying that his tablets are in no sense intended for "cram," and if properly employed as adjuncts to practical dissection they cannot but help greatly in giving a student such a knowledge of anatomy as will be of use to him, not merely in his examinations in that subject, but also in the study of surgery and in practice itself. The present edition differs from its predecessors chiefly in the large number of illustrations (both coloured and uncoloured) which it contains; these have been culled from a wide area and include very many of those with which we are all familiar in the ordinary text-books of anatomy but which nevertheless help to make clear the statements contained in the text.

LIBRARY TABLE.

A Report on Vaccination and its Results, based on the Evidence taken by the Royal Commission during the Years 1889–1897. Vol. I. The Text of the Commission Report. London: New Sydenham Society. 1898. Annual subscription to the Society, 21*s.*—Many will be glad that the New Sydenham Society should have proceeded to include in its series of publications some account of the labours of the recent Royal Commission on Vaccination. Life is at once too short and too full to permit the majority of our profession to study the six or seven bulky blue-books with their reports of evidence and their voluminous appendices which represent that Commission's work. Yet it would have been a pity had the salient facts elicited during that prolonged inquiry not been made more generally available. This first instalment by the society consists merely of a reprint without note or comment, and we regret to say also without index, of the text of the final report and the report of the dissentients. These documents are historical and are most valuable from the masterly manner in which the whole subject is surveyed in them. It would have added to the interest of the volume had it been prefaced by some account of the reasons for the appointment of the Commission and of the members composing it. We learn from a notice prefixed to this reprint that the New Sydenham Society proposes to include in another volume extracts from the evidence.

A Simple Method of Water Analysis; especially Designed for the Use of Medical Officers of Health. By JOHN C. THRESH, M.D. Vict., D.Sc. Lond., D.P.H. Camb. Second edition, enlarged. London: J. & A. Churchill. 1898. Price 2*s.* 6*d.* — The simple method here described was outlined in an annotation in THE LANCET of Jan. 23rd, 1897. We predicted that medical officers of health would find the method convenient and fairly accurate. We were not mistaken, since Dr. Thresh has found it already necessary to issue a second edition with an additional section on the examination of sewage effluents. The standard of purity adopted in this case is that dependent upon the oxygen-consuming power as shown by permanganate. A better standard is based on the amount of nitrates and a little more stress might have been laid, we think, on the significance of nitrates in sewage effluents. As applied to water analysis we have found the "simple method" very useful in affording a preliminary and reliable indication of the fitness or unfitness of a given water for potable purposes. In the event of the latter conclusion being formed a more elaborate analysis may be carried out. Messrs. Burroughs, Wellcome and Co. supply a neat and portable case containing the necessary reagents in the form of "soloids."

WE wish to draw attention to an announcement of the *Times* reprint of the "Encyclopædia Britannica" which is inserted in this issue of THE LANCET and which may be worth the attention of our readers as affording to those who desire it an opportunity to obtain a well-known work of reference at a great reduction on the price usually charged.

JOURNALS.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D. Cantab., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. xxiii. Nos. 1 and 2. London: C. J. Clay and Sons. June 10th, 1898. Price 8*s.*—This part contains the following articles: 1. John Berry Haycraft, M.D., D.Sc. Edin., upon the Production of Rapid Voluntary Movements, with 8 Figures in the text. 2. W. M. Fletcher, M.A., The Survival Respiration of Muscle, with 47 Figures in the text. 3. J. S. Macdonald, Demonstrator, and E. Waymouth Reid, Professor of Physiology in University College, Dundee, N.B., Electromotive Changes in the Phrenic Nerve: A Method of Investigating the Respiratory Centre, with 9 Figures in text. 4. W. B. Warrington, M.D., M.R.C.P. Lond., On the Structural Alterations Observed in Nerve Cells, with 1 Plate and 4 Figures in the text. 5. F. Gowland Hopkins, M.B. Lond., and S. N. Pinkus, Ph.D., Observations on the Crystallisation of Animal Proteids.

THE LANCET.

LONDON: SATURDAY, JULY 23, 1898.

IN THE LANCET of July 2nd we printed a letter from Mr. GEORGE JACKSON, in which he stated that he had addressed to the candidates for the vacancies upon the Council of the Royal College of Surgeons of England certain questions, among others one bearing on the present method by which the representative of the College upon the General Medical Council is chosen by the Council of the College and not by the corporation as a body. It will also be remembered that, as was reported in THE LANCET of June 18th, Mr. R. B. ANDERSON has lately proposed to test by a friendly suit at the expense of the College the legality of the action of the Council of the College in selecting such a representative, he in common with other Fellows and Members of the College considering that a right to exercise a franchise has been and is conferred upon him by the Medical Acts: but Mr. ANDERSON found the Council unwilling to undertake the costs of both sides to the action. We are not prepared, at any rate at the present moment, to express any opinion upon the true meaning of the passage in the Acts upon the wording of which those who take this view are relying, and we strongly counsel Mr. ANDERSON, and those associated with him in the attempt to make good the right of the corporation as a body to choose their representative on the General Medical Council, to abstain from legal subtlety in their arguments. The law of the land must, of course, be administered exactly, but the work of reform does not prosper while it relies upon verbal and technical interpretations, even if those interpretations are correct. No large body of responsible and worthy adherents will be found ready to join in an agitation which trusts for its justification to the rendering of a phrase, while hundreds might join such an agitation in defiance of the wording of all the Acts of Parliament in existence if they could be persuaded that such a course was in accord with justice and expediency.

The representatives of the various universities and corporations upon the General Medical Council are chosen as follows:—

1. The University of Oxford: elective body, Convocation, which consists of every member of the rank of M.A. who has kept his name on the books and duly paid his fees and duties.
2. The University of Cambridge: elective body, the Senate, the constitution of which is practically the same as that of the Convocation of Oxford.
3. The University of London: elective body, the Senate, which consists of the Chancellor, the Vice-Chancellor, and the thirty-six Fellows.
4. The University of Durham: elective body, Convocation on the nomination of the Senate. The constitution of the Senate is the Warden, sundry Professors, the Master of University College, the Principal of Hatfield Hall, and six other members of Convocation. The Convocation is much the same as that of Oxford or the Cambridge Senate.
5. The Victoria University: elective body, the Council, which consists of the Chancellor, Vice-Chancellor, and various other members, of whom only two are even indirectly elected by the Convocation of the University.
6. The University of Edinburgh: elective body, the University Court, consisting of the Rector, the Principal, and three or four assessors appointed by the Chancellor, the Rector, the University Court, and the Senatus Academicus.
7. The Universities of Glasgow, Aberdeen, and St. Andrew's elect in the same manner and under the same constitution as the University of Edinburgh. At Glasgow the University Court includes the Dean of Faculties, an officer elected annually by the Senate.
8. The University of Dublin: elective body, the Provost and Senior Fellows of Trinity College, Dublin.
9. The Royal University of Ireland: elective body, Members of the Senate by open voting. The Senate consists of the Chancellor and thirty-six Members all appointed by the Crown.
10. The Royal College of Physicians of London: elective body, the Fellows sitting in full Comitia.
11. The Royal College of Surgeons of England: elective body, the Council every fifth year. The Council consists of the President, two Vice-Presidents, and twenty-one Fellows.
12. The Apothecaries' Society of London: elective body, the Court of Assistants.
13. The Royal College of Physicians of Edinburgh: elective body, the Fellows in open voting.
14. The Royal College of Surgeons of Edinburgh: elective body, the Fellows.
15. The Faculty of Physicians and Surgeons of Glasgow: elective body, the Fellows.
16. The King and Queen's (now the Royal) College of Physicians of Ireland: elective body, the President and Fellows in annual meeting.
17. The Royal College of Surgeons in Ireland: elective body, the Council, consisting of twenty-one Fellows.
18. The Apothecaries' Hall of Ireland: the representative is elected at the annual meeting of the society.

It will be seen from this list that while the elder universities, such as Oxford and Cambridge, place the voting for a representative upon the General Medical Council in the hands of all members of the universities who are no longer *in statu pupillari*, the younger and more frankly democratic corporations, such as the University of London and the Victoria University, find it advisable to restrict the power of voting for a representative to a much more select body.

From this list, also, it is plain that whatever the corporation of the Royal College of Surgeons of England suffer as a body by the present method of the election of their representative upon the General Medical Council, they suffer it in common with many other bodies—a position of affairs which was, as a matter of fact, taken into account when direct representatives of the medical profession were first elected to the General Medical Council. Perhaps the wording of a charter may give an advantage to one body over another, but the medical profession as a whole are not likely to consider that this would form a good basis upon which to start an agitation for reform. As we have already said such movements only become serious and attract responsible persons when their promoters can prove that justice and expediency as well as the literal right are on their side. For the present let us leave out of consideration the justice of the demand that the Fellows and Members of the Royal College of Surgeons of England should select their own representative on the General Medical Council—an exception which we are able to make in this airy manner in that our readers know that we have unceasingly advocated the claims of the Members and Fellows alike to just treatment in their College and that we shall never disregard justice in these matters because for the moment it seems inopportune to discuss it in the abstract. We come to expediency. It is for those who

Digitized by Google

desire a change in the existing methods to show that the profession of medicine as well as the Royal College of Surgeons of England would gain by the proposed reform. They must, if they wish for converts, show that the College and the profession are not only aggrieved in this matter but that the grievances will be abated under the suggested innovation. If the Council of the Royal College of Surgeons of England were elected by the College, as it should be, instead of by a small class of the College, the Council would be a proper body to select the representative of the College upon the General Medical Council. But the Council being elected only by the Fellows, who constitute a comparatively small part of the body corporate, its choice of a representative becomes open to criticism. In our opinion all efforts towards the reform of the College should be directed towards making its Council truly representative of the corporation, so that the point upon which Mr. ANDERSON desires a legal decision seems to us to be of secondary importance.

THE Executive Committee of the General Medical Council had under consideration several important questions at its meeting on July 12th. For the most part these arose out of resolutions of the Council itself in May last. Perhaps the most important of these had reference to a very much needed amendment of the penal clauses of the Medical Act. All parties in the profession and the General Medical Council itself are agreed that these clauses need amendment. There can be little doubt that the public itself must be of the same opinion with the profession up to a certain point. There may be differences of opinion as to how far such amendments should be carried, and we are well aware that the public are jealous of the restriction of personal liberty even in the case of unscrupulous quacks. But there is practical unanimity that the medical profession should be defined and that the titles which imply medical qualifications and status should be protected. The Council on May 31st last resolved that its President should be requested to communicate with the Lord President of the Privy Council as to the practicability of obtaining such an amendment of the law as would more effectually prevent the holder of any medical degree or diploma from using the title thereof after his name had been erased from the Medical Register under Section 29, and for so long as the erasure continued in force. It seems obvious that a person who has been guilty of professional conduct so gross as to induce the General Medical Council to remove his name from the Register should not be allowed to flaunt before the public titles which convey the impression that he is still on the Register. If ever there was any doubt on this point it must surely have been dispelled by recent events. Within the last few weeks public attention has been directed to the painful case of a graduate of a university who has committed more than one crime and is now sentenced to imprisonment for seven years. By his very situation he is prevented from doing further mischief to HER MAJESTY'S subjects or further dishonour to his university and his profession. His profession has cleared itself of all connexion with him through the act of the General Medical Council in removing his name from the Medical Register. But, strange to say, he still continues to be a graduate of the Royal University of Ireland. There is no reason to believe that the Royal University of Ireland wishes to retain such a graduate on its rolls. Indeed, there is no doubt that all the universities of the country and all the medical corporations are desirous of such an amendment of the law as will prevent a graduate or a diplomate so erased from using his titles *so long as the erasure continues*. We italicise these words as showing the justice and mercy of the bodies and the profession which, through their representatives in the General Medical Council, have with practical unanimity asked for this amendment. There are offences and there are crimes. There are cases in which removal from the Register is only temporary, in which the Council properly exercises its clemency and restores the names which it has erased. In any amendment of the law provision for such restoration of status to the holders of degrees or diplomas should be carefully made. But during the period of erasure the qualifications and the titles attaching to them should clearly be suspended too.

It is somewhat discouraging to find from the words of the reply to the communication of the President contained in the minutes of the Executive Committee that the Lord President of the Council "cannot hold out any hope of legislation being undertaken to effect amendment of one provision of the Medical Act, even if the degree-giving bodies had expressed a desire for the amendment, which does not appear to be the case." The last words of this quotation show that the Lord President is of opinion that the universities at least do not wish for the amendment asked for by the General Medical Council. We feel sure that the Lord President will ascertain exactly the truth in this matter. It cannot be the wish of the universities to have their degrees and titles used by graduates who have discredited them, and, as a matter of fact, as we have said, through their representatives the universities are parties to the communication to the Lord President on this subject from the General Medical Council. We are glad to note that the Executive Committee have not regarded the answer of the Lord President as final and have requested Sir WILLIAM TURNER to put himself into furthe communication with the Clerk of the Privy Council on this matter. The President's own action on the subject has been so careful and judicial—we might almost say cautious—that he may be safely trusted to place before the Lord President the serious aspects of the present defects of the law and the urgent need for its amendment.

The minutes of the Executive Committee show that a communication had been received from the Home Secretary in reference to projected legislation for the regulation of so-called massage establishments at the instigation of one of the vestries of London in whose district such institutions threaten to be a cause of scandal. The Home Secretary seems to have thought that the freedom of the medical profession or its rights might in some way be prejudiced by such legislation and very properly directed the attention of the General Medical Council to it. The Executive Committee have replied that in their opinion the regulation of such establishments is essentially a police question and one in no way affecting the medical profession which does not need them. We feel persuaded that such an answer will have the approval of the profession.

Digitized by Google

Massage is a very useful thing in its place, but, like every other detail of treatment, it is unduly magnified by those who do not see it in its proper proportions and relation to other means of treatment, and it is clearly being used in many directions for immoral and disgraceful purposes. The medical profession will take its own means of procuring massage for those who need it and the Home Secretary need fear no opposition from the profession or injury to it in legalising any police measures for the punishment and restraint of those who prostitute massage to base purposes.

THE case of KINGSBURY and Another *v.* HOWARD, which came to an end on Tuesday last after a hearing lasting six days, presents many features of interest to medical men. The story has been so widely circulated in the lay press that we need only give its outline here. Dr. KINGSBURY, a medical practitioner at Blackpool, attended assiduously the late Mrs. HOWARD, an old lady who made him a residuary legatee under her will whereby he should benefit to the extent of £30,000 or more. He attempted to hypnotise her in the course of his medical treatment of her on twenty-two occasions, and the will was disputed on the ground that he had exercised undue influence over her, that, in fact, he had "suggested" to her when in the hypnotic state the advisability of making him her legatee. Of evidence that Dr. KINGSBURY had so hypnotised Mrs. HOWARD there was not a scrap, while he denied that he had ever been able to produce any effect upon her in his numerous attempts. It was shown by a will dated before the hypnotic experiments had commenced that Mrs. HOWARD intended to benefit Dr. KINGSBURY, nor was there anything very unnatural in the generous bequest of the deceased to her medical attendant, for Mrs. HOWARD'S only surviving son was already wealthy and was on unfriendly terms with his mother, while Dr. KINGSBURY took nothing until after substantial donations had been set apart for charities. Under these circumstances, as Mr. Justice GORELL BARNES pointed out to the jury in his summing-up, the whole case depended upon whether the jury believed Dr. KINGSBURY'S evidence or not. Dr. KINGSBURY said that he had never hypnotised Mrs. HOWARD, often as he had attempted to do so, and the denial was borne out by Mrs. HOWARD'S confidential servant. The jury found that the will in question, the last of many wills, had been duly executed; that the deceased was of sound mind, memory, and understanding; that she knew and approved its contents; and that the residuary clause under which Dr. KINGSBURY was so large a beneficiary had not been obtained by undue influence. This finding of the jury exonerates Dr. KINGSBURY from the odious charge of having grossly abused the fiduciary position which he occupied towards his patient, and also, to our thinking, inflicts a serious blow upon the claims of hypnotism. The jury arrived at their decision either because they believed Dr. KINGSBURY, who said that he had failed to hypnotise the patient in spite of repeated trials; or because they were unwilling to allow that the power of hypnotic suggestion could be used to sway the testamentary intentions of a sane person; or, most probably, by looking at all the circumstances, from both these points of view. Now Dr. KINGSBURY is an experienced hypnotist who has given exhibition of his powers before assemblies of his fellow practitioners, so that it is damaging to the prestige of hypnotism as a therapeutic agent to learn that so accomplished a professor of the art or science after repeated trials was unable to produce any effect upon an old and sick lady. Again, if the contingency that Mrs. HOWARD might be influenced by hypnotic suggestion so as to deal with her money in what was, after all, no very unnatural manner has seemed incredible to a jury, what would a jury say to the more advanced claims of hypnotism? We have all heard of subjects in the hypnotic state who, though of unblemished character, have cheerfully committed crimes, or rather the simulation of crimes, at the suggestion of the hypnotiser, and experiments with these sensational tendencies have been reported in medical journals and find a place in scientific literature. We do not envy the medical man who is called upon in the witness-box to assist a jury at arriving at a decision upon the credibility of any such situation arising in ordinary life, but we think that he would be quite justified in declining to commit himself to any definite opinion in the present state of our scientific knowledge. And the case of KINGSBURY and Another *v.* HOWARD lends force to our advice.

Annotations.

"Ne quid nimis."

THE VACCINATION BILL: A CHANGE OF FRONT.

ON Tuesday evening the Vaccination Bill was under consideration as amended by the Standing Committee on Law and during the debate Sir Walter Foster proposed a radical amendment. He desired to add after Clause I. a new clause allowing the parent or person in charge of an infant who makes a statutory declaration of conscientious objection to vaccination before two magistrates to be exempt from all proceedings taken with reference to the non-vaccination of the child. The suggested clause practically did away with the compulsory element, so following the spirit of the recommendations of the Royal Commission. Mr. Balfour promised that an amendment should be introduced covering the ground of Sir Walter Foster's proposed clause, believing that every reasonable attempt should be made to get a Vaccination Act which was satisfactory to the sense of the House and not one which was passed by a mere party majority. As a new clause to a Bill cannot be moved when the Bill is in the report stage without notice the debate was adjourned until the Government amendment was formulated. On Wednesday evening Sir Walter Foster withdrew his amendment in favour of the following amendment, which he considered practically identical in principle with his own, and which was moved as a new clause to the Bill by Mr. Chaplin:—

"No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act of 1867 if within four months from the birth of the child he satisfies two justices in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child, and within seven days thereafter delivers to the vaccination officer for the district a certificate by such justices of such conscientious objection."

After some debate had arisen on the wording of the end of

Digitized by Google

the clause, the clause was added to the Bill. For all practical purposes compulsion has therefore gone by the board.

THE CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

RIVALRY in business is generally considered to be a benefit to the public, but it is a question whether the rivalry of the numerous sanitary associations is not of less general advantage than would be their amalgamation. Unity is strength and the multiplication of societies all interested in one art or one science weakens the whole. Even if the obstacles in the way of combination are insuperable an agreement upon certain points would be an advantage. Neither the Sanitary Institute nor the Royal Institute of Public Health holds annual congresses and exhibitions; why not, therefore, have them in alternate years instead of both in the same year? The one undoubtedly detracts from the other, and more than one sanitary authority, confused by the multiple requests to appoint delegates, have decided to send delegates to neither. We have already referred to the congress of the Sanitary Institute which is to be held in Birmingham in the autumn and we have now to direct attention to the congress of the Royal Institute, which will be held in Dublin next month. The President is Sir Charles Cameron, M.D. R.U.I., and the Lord Mayor of Dublin is the Honorary President. The Presidential address will be given in the Examination Hall, Trinity College, at noon on Aug. 18th, and the business of the congress will not conclude until the 23rd. Dr. Grimshaw, C.B., will preside over the Section of Preventive Medicine and Vital Statistics; Professor J. W. Moore over the Section of Chemistry and Meteorology; Mr. C. P. Cotton (Local Government Board) over the Section of Engineering and Building Construction; and Alderman the Right Hon. J. M. Meade, P.C., over the Municipal and Parliamentary Section. There will be conferences of naval and army medical officers, of medical officers of health, of sanitary inspectors, and of veterinarians. An exhibition of sanitary appliances is also being organised. The generous impulse of the local executive, so characteristic of the inhabitants of the Emerald Isle, has provided an unusual round of festivities. Everything indicates that the Congress will be a success and if any further inducement is necessary to attract visitors it will be found in the fact that the world-famed Horse Show will open on the closing day of the Congress.

ARTIFICIAL EYES.

ACCORDING to a German authority people wearing false eyes must be pretty nearly as common as the remainder of the victims collectively whom fate has deprived of a portion of their bodies, be it organ or limb. Every year, we are told, no fewer than 2,000,000 of glass eyes are manufactured in the German Empire and it is, of course, far from probable that the whole of the world's supply should be made in Germany. On the contrary it is stated in *La Médecine Moderne* that a single French firm turns out at least 300,000 glass eyes annually, and that there are several other factories in France the output of which is about the same. How, it will naturally be asked, can this enormous stock be utilised? Glass eyes although essentially brittle are little liable to injury, do not wear out quickly, and are quite independent of the vagaries of fashion. Once suited the owner of a glass eye may make it serve him a considerable time. A writer in the *Journal d'Hygiène* is disposed to regard the oculiform millions as a fantastic creation, seeing that one-eyed people are rare comparatively speaking and that the majority of them do not wear false eyes; but a little consideration should suffice to show the critic that his doubts are not well founded. Like many an objector he assumes the premisses—to wit, that all the eyes are used to replace human losses, whereas most likely false eyes of every description are included in the list. Evidently taxidermists, bird-stuffers, the makers of wax figures, &c., must use an immense quantity, to say nothing of the artists who are responsible for the innumerable army of dolls large and small. Viewed in the light thus thrown upon the matter the 2,000,000 which seemed to be so amazingly beyond the mark dwindle to a mere bagatelle—a mere drop, so to speak, in the ocean of false eyes. In this connexion allusion to the singular fact that it is only the one-eyed who seek to conceal their deficiency by means of a substitute may be permissible. The totally blind never wear false eyes, or if an instance now and then occur it merely serves to prove the rule. In consequence of his æsthetic sense a one-eyed man feels compelled to endure the discomfort which in greater or lesser degree attends upon every foreign body which has obtained lodgment in the human economy, but the man who has lost both his eyes is free from this weakness—his æsthetic sense expired along with his vision.

THE CHELSEA PHYSIC GARDEN.

A REMEMBRANCE of pleasant hours spent at the Apothecaries' Physic Garden at Chelsea is part of the heritage of many of the London medical students of thirty years ago. At that time the diplomas which they usually sought were the Membership of the College of Surgeons and the Licence of the Apothecaries' Society. Medical botany was part of the usual curriculum and some knowledge of the officinal plants named in the British Pharmacopœia was an important matter for the candidate at "the Hall." Every week fresh specimens were sent from Chelsea to Blackfriars. The wary candidate, if well advised, visited the Physic Garden during the week preceding his examination, and he possibly consulted one of the gardeners as to the plants which were at the time in their most characteristic state; he then noted their leading peculiarities, so that he could again recognise or, as it was colloquially called, "spot" the specimens and, by the help of Sir Alfred Garrod's Manual and other text-books, mention the virtues credited to them. Of late years, rightly or wrongly, medical botany has been supplanted by other studies and the Society of Apothecaries has now applied to the Charity Commissioners as to the future regulation of the Chelsea Physic Garden, of which they were trustees under the will of Sir Hans Sloane. The trustees of the London Parochial Charities having offered to maintain the garden for the purposes of botanical study the Charity Commissioners will shortly publish a scheme giving general effect to the proposed change of management.

AN AMERICAN VIEW OF THE ABUSE OF MEDICAL CHARITY.

THE *Yale Medical Journal* for June contains a valuable and suggestive paper on "The Existing Abuse of Medical Charity and How it Can be Remedied,"[1] by Frederick Holme Wiggin, M.D., Visiting Gynæcologist to the New York City Hospital. Dr. Wiggin gives a short history of the origin and growth of the out-patient system and traces it to St. Bartholomew's Hospital, London, where a system of out-door relief was established in 1770, known as the dispensary, the object of which was "the relief of the sick poor without regard to place of abode who are able to visit the hospital, *but unable to pay the expense of a medical attendant at*

[1] The paper was read before the Connecticut Medical Society at New Haven on May 26th, 1898.

Digitized by Google

home." Philadelphia followed suit in 1788. New York copied Philadelphia in 1790, the promoters being the Medical Society of New York. Dr. Wiggin is indebted for his history and statistics mainly to a recent report of a special committee of the New York State Board of Medical Charities appointed to examine into the method of giving medical relief to the sick poor through dispensaries. The evil has grown over since and is as bad in New York as it is in London, but the unhealthy development of it dates from 1862. It is interesting to notice Dr. Wiggin's view of this evil development. It began with the establishment of clinics, which were to all intents and purposes dispensaries, where no question was asked concerning the patients' means or residence so long as the case was interesting and the patient was willing to exhibit his disease to students. It ignored territorial considerations of district and social questions and distinctions of wealth. Outdoor departments of hospitals followed and these in turn were followed by dispensaries which aimed at publishing numbers rather than at fine discriminations of the needy. Then the churches entered into competition and had their dispensaries, the main object of which was "not the care of the sick poor, but to increase the number of Church adherents." Now Dr. Wiggin considers it is established that not far from 50 per cent. of all applicants for free medical relief in the larger cities are not persons who require aid. A factor in the case is the physician, with his natural desire to do good and to be generous to those in trouble—a desire sometimes accompanied with a disregard of the rights of those nearest to him. The remedies he finds in the education of the laity, in paying physicians of charitable institutions, and in placing all such institutions under a State Board with a central bureau by which individual cases shall be systematically but considerately investigated. Dr. Wiggin's State Board would correspond somewhat to our idea of a Central Hospital Board. We do not give our approval to any State interference nor are we prepared to endorse a sweeping resolution of the Litchfield County Medical Association of which Dr. Wiggin approves, entirely condemning the acceptance by medical men of all contract relations with lodges, societies, and similar organisations as contrary to all ethical medical principles. We must not be unpractical. We must recognise great organisations of working men. But we must imitate them in our organisation and in demanding suitable terms.

THE LIMITS OF A LANDLORD'S LIABILITY.

A CASE of some importance as bearing on the legal liability of landlords in respect to the sanitary condition of dwellings let to tenants was heard before the Lord Chief Justice at the recent Bristol assizes. The plaintiff (Mr. J. W. North, A.R.A.) claimed damages from his landlord (Mr. Wm. Wyndham) in consequence of defects in the drainage of Beggearnhurst House, Washford, which had been tenanted by Mr. North since 1884. The house was an old one, but no grave cause of complaint arose until 1894 when defects were discovered and on application were supposed to have been made good by defendant's workmen. The work, however, was improperly done, so that sore-throats and other sickness continued to prevail in the household, and in September, 1897, Mr. North lost one of his children from diphtheria. Mr. Brettingham, the medical officer of health of the district, pointed out very serious defects and advised the entire reconstruction of the drainage and the removal of a water-closet situated in the middle of the building. The question at issue was as to how far the landlord was liable for the original faulty construction of the drains and also whether the tenant could claim any compensation in the absence of any specific agreement at the time of entering upon his tenancy. The case was compromised, the defendant consenting to forego one year's rent, each party paying his own costs. The judge informed the jury that if a man took a furnished house the law implied that the house should be reasonably fit for habitation, which included that there was nothing in the state of the drains which would affect the health of the inhabitants. But there was no such understanding implied in the letting of an unfurnished house, and without an expressed undertaking on the part of the landlord the law assumed that the tenant took the premises "for better or worse." In this particular case, much as Mr. North had suffered, there was no evidence that Mr. Wyndham was not ready to do all that he could be reasonably required to do in remedying defects which were pointed out. The moral then to be drawn from this judicial deliverance is that a would-be tenant of an unfurnished house must be careful to obtain from his landlord an agreement or warranty that the dwelling is in a fit state for habitation unless he wishes to run the risk of exposure to the effluvia from ill-constructed drains which may not be discovered until he has been some time in possession. In particular should he be careful when dealing with old houses where the sanitary arrangements may be the reverse of satisfactory and where even cesspits may still exist in close proximity. He must remember that no claim for compensation for damage due to such insanitary conditions will lie unless he has previously guarded his interests in some such manner. Better still would be the insisting as an essential preliminary to his possession of the premises that their sanitary condition should be thoroughly investigated and made good.

RECURRENCE OF TYPHOID FEVER IN CHICHESTER.

CHICHESTER is again suffering from typhoid fever and a number of memorialists are asking for the intervention of the Local Government Board. Just the same took place in the autumn of 1896, when, in answer to appeals from the locality, the Local Government Board instructed Dr. Bulstrode to make an investigation into the matter. The result was a searching investigation and a very able and convincing report. The issue of this report was followed by experiments made at the cost of the State into the nature of Chichester soil as a breeding ground for the typhoid bacillus, with the result that when soil was collected from areas where fever is ever recurring in Chichester it was found that after sterilisation its inoculation with the typhoid organism showed that it contained everything necessary to the persistence of this disease organism in a form potent for mischief. In fact, there are parts of Chichester which are sodden with ancient filth and in which typhoid fever recurs from time to time. The corporation, however, themselves made a report showing that all was *couleur de rose* in their ancient city; that the city had "been grossly misrepresented by foreign officials"; and that the town council was "hampered and annoyed by unnecessary and troublesome interference ..... and unjustifiable intermeddling in local self government." It was not, therefore, likely that they would act on the advice which the central authority tendered through their inspector, and now the same disease prevails again and the inhabitants are appealing against their own rulers and asking for another Government inspection. Some sort of inquiry has apparently been promised, but if it takes place it is to be hoped that it will be of an exhaustive character and that it will take close account of the "local self government" system which has brought about a state of affairs in which a portion of the inhabitants seem to have lost all confidence in those who have the sanitary control of the city. There is, however, one aspect of this state of affairs which must be settled locally. The system of local self government which the town council claims to carry out unhindered involves the election of

Digitized by Google

councillors by the voters, and if it be really true that the memorialists represent a substantial number of the citizens it will be quite easy for them to show that they mean what they say at the next municipal election. The *Chichester Observer* of July 6th states that "the medical officer has recommended a house-to-house inspection, but the matter proceeds no further." Since it rests with this officer to advise the council as to what is necessary, and since he has the responsibility of determining what are the causes of disease in his district, it is very ominous to find that when he gives his advice "the matter proceeds no further." In view of the present aspect of affairs it may be asked by some why Chichester should receive State aid at which its represen tatives scoff, whilst other districts who would gladly get the advice of independent central experts are often denied that help on the ground of an insufficiency of staff.

THE JUBILEE OF W. G. GRACE.

AT fifty years of age a man's natural force may presumably be supposed to be abating. As medical journalists we are naturally interested in seeing the incomparable "W. G." apparently as well able as ever he was to stand a long day's fielding, to get runs, and to take wickets. The complicated muscular movements and the absolute correspondence of hand and eye which playing sound cricket requires are only to be really appreciated by those who understand anatomy and physiology. We are therefore all the more interested in Mr. Grace's success, for although his fame has been won on other fields than those of the laboratory and the sick room we all remember with pride that he is a member of the profession of medicine and hence we have a double reason for offering our congratulations to one who has shown himself so proficient in every department of the national game.

ENANTHEMATA.

AT the annual meeting of the American Pediatric Society held in Cincinnati in the beginning of June Dr. F. Forchheimer, of Cincinnati, read a paper on what he considered to be a characteristic enanthem of German measles. According to the extract published in *Pediatrics* the enanthem is a macular, distinctly rose-red eruption upon the velum of the palate and the uvula, extending to, but not over, the hard palate. The spots are arranged irregularly, not crescentically, are of the size of large pin-heads, and are very little elevated above the level of the mucous membrane. He studied the eruption in 22 cases. In no case had he seen the exanthem when there was not present a suggestion of the enanthem. The enanthem is very short-lived, fading away within the first 24 hours. It is the same eruption which is found upon the skin, characterised by the size of efflorescence, its arrangement, the absence of great infiltration, and, above all, by its colour, a pure pinky-rose-red, almost exactly the same as the "roseola" of typhoid fever. During the process of involution there are sometimes left pigmented deposits, usually of a yellowish or yellowish-brown colour, either in the form of spots or streaks. The difference between this enanthem and those of scarlet fever and measles is as follows: in scarlet fever the enanthem appears from twelve to twenty-four hours before the eruption. It appears on the pillars of the fauces in the form of characteristic puncta, then rapidly spreads over the mouth in the form of a scarlet-red coalescing eruption, which ends in desquamation, producing the strawberry tongue. In measles the enanthem begins upon the soft palate from thirty-six to forty-eight hours before the exanthem in the form of purplish papules arranged crescentically. Some of the subsequent speakers said that their experience confirmed that of Dr. Forchheimer and Dr. Jacobi made a reference to the enanthem described by Koplik in measles, a report on which was published in a recent number of the *Deutsche Medicinische Wochenschrift*.

THE HAMPSTEAD HEATH EXTENSION SCHEME.

THE Lord Mayor presided on Tuesday over a public meeting at the Mansion House in furtherance of this scheme at which the speakers included the Marquis of Lorne, Lord Knutsford, Sir Samuel Wilks, Lady Jeune, Mr. Seymour Lucas, R.A., Canon Ainger, and Sir Henry Harben. Motions were carried unanimously approving of "the endeavour that is being made to preserve the beauty and extend the area" of Hampstead Heath and calling "upon the public to accord a generous response to the wider appeal that is now being made." Yesterday (Thursday) Sir Henry Harben, chairman of the local committee of the Hampstead Heath Extension Scheme, received a large number of visitors at Golder's Hill during the afternoon, the result of which informal garden-party should be a large accession of subscriptions.

IRREGULAR MEDICAL PRACTITIONERS.

IN the House of Commons on Tuesday last Dr. Farquharson asked the Chancellor of the Exchequer the following question: "Whether, having regard to the fact that a sum of £5000 a year of public money is paid to the Council of the Incorporated Law Society to assist them in purifying the legal profession, he could see his way to make a similar grant to the General Medical Council to enable them to undertake the prosecution of irregular medical practitioners." The Chancellor of the Exchequer said that the sum granted to the Council of the Incorporated Law Society was £2500 and was only a small fraction of the yield from the special duty on solicitors' certificates which went to the Exchequer. No such tax was imposed upon medical practitioners and therefore no question of a similar grant to the General Medical Council arose. Dr. Farquharson must have known that his question would elicit this obvious reply. We hope that he will not be deterred from making further moves in this and other directions towards obtaining for the General Medical Council further powers.

THE X RAYS IN MILITARY SURGERY.

PROFESSOR KÜTTNER of Tübingen, who followed the last Greek war in connexion with the German Red Cross Society, has made some interesting experiments with the Roentgen rays at the Constantinople Hospital. In his report, just issued, he says that while the apparatus proved of service when applied with the screen it was rarely possible to take a satisfactory photograph on account of the difficulty of bringing the patients into the proper position. The former method proved often the only way to ascertain the site of a projectile which had entered the body and had remained there. This was applicable to all parts of the body except the stomach and head. A bullet in the brain, for instance, showed very indistinctly. (Last spring an arrangement of mirrors was exhibited at a soirée of the Royal Institution where a photograph of the brain showed in relief, thus enabling the operator not only to see the foreign body but also to measure correctly its distance from the outer wall of the cranium.) Professor Küttner says it is noteworthy that splinters of bullets and of bone which had penetrated into the soft parts of the body could not be distinguished from each other. Also, he says, it was proved that the opinion that deep-lying masses of pus could be located was erroneous. Injuries to the central nervous system, the spinal cord, and the peripheral nerves were solely ascertainable by the aid of the Roentgen rays. It was impossible

Digitized by Google

to do this before. Furthermore, it could be seen whether a bone was totally or only partially severed—a matter of great importance as far as therapeutics are concerned. For shot-wounds in the extremities he recommends that a photograph be taken. His conclusion is that the Roentgen rays are of great importance for medical aid in war, but only for fixed hospitals, such as reserve hospitals and those installed in fortresses, while for moving field hospitals their application is very limited.

THE LATE MR. GREIG SMITH.

WE publish this week a clinical lecture from the pen of the late Mr. Greig Smith, whose lamented death last year, at the early age of forty-three years, deprived our profession of one of its ablest members and the Medical School of Bristol of a most competent and energetic teacher. Mr. Greig Smith had accomplished much in his comparatively short career—enough to have satisfied many men—but in the opinion of all who knew him he would have gone much further. The paper which we issue to-day (the illustrations to which have only recently reached our hands) bears evidence to Mr. Greig Smith's lucidity as a teacher and skill as a draughtsman, as well as to the extreme thoroughness of his work.

"THE LESSON OF MIDDLESBROUGH."

IN a letter to an evening journal under the above heading Mr. Alexander Paul claims that the statistical results of the recent epidemic of small-pox at Middlesbrough just issued by Dr. Dingle, medical officer of health, prove that the "case for vaccination" has "utterly broken down." We desire to say nothing to Mr. Paul's discredit. We recognise in him a fair-minded advocate of a hopeless cause, one, too, who has never stooped to the methods of personal defamation which disfigure the writings of most anti-vaccinationists. Honest himself he gives credit for the honesty of his adversaries in pleasing contrast to the spirit of some of his party. We do not therefore wish to pass by his criticisms in silence but to act as fairly by him as he endeavours to do by us. Yet we would have Mr. Paul remember that the bias which he has against vaccination is quite as potent a factor in his conclusions as any bias may be in the other direction. For what is his argument? According to Dr. Dingle, of those attacked by small-pox 1207 had been vaccinated—a proportion of about 1·3 per cent. of the whole vaccinated members of the community; 198 had never been vaccinated—a proportion of about 11·7 per cent. of the unvaccinated population. The fatality-rate amongst the vaccinated was 8·8 per cent.; amongst the unvaccinated 47·4 per cent. Mr. Paul explains these striking divergencies very simply. The small section of Middlesbrough folk who had escaped vaccination were, he avers, more susceptible to small-pox and to fatal attacks not because they had not been vaccinated (for that is a useless rite), but because they are made up of the "leavings" of the population—the weakly infants, the neglected and the tramp class. Otherwise, he says, it is not credible that nearly one-half of those attacked should have died. This "pure assumption," to use his own phrase in another connexion, is, we suspect, but half a truth, for it cannot apply to places where the majority of the children are unvaccinated and yet they have died (strong and weak alike) in similar proportion when attacked by small-pox. There is no fixed fatality-rate for small-pox or any other epidemic disease; it varies from time to time and from place to place, and though we may admit that 47·4 is excessively high we suspect that in pre-vaccination days it was often just as high amongst the parallel class. But why does Mr. Paul ignore the comparative incidence and fatality amongst the vaccinated and the unvaccinated at similar age-periods? Why does he suppress the evidence adduced as to the comparative severity of attacks in the two classes? Lastly, why does he contemptuously dismiss the explanations frankly given by Dr. Dingle as to the failure of revaccination to protect in all cases? He writes as if he were impartial, but his tone is that of the advocate, not of the judge. The case for vaccination must depend upon the fulfilment of those conditions which point to its being effectively carried out. The anti-vaccinationist naturally ignores all this, for to him vaccination is nothing but a "filthy rite." But no one who approaches the subject with as much freedom from bias as is possible to fallible humanity can arrive at any other conclusion than the one which was attained by the Royal Commission, which is forced upon all who have personal knowledge of small-pox and is proved by the experience of every civilised nation in the world.

THE EXPENDITURE OF THE METROPOLITAN ASYLUMS BOARD.

DR. FARQUHARSON deserves the thanks of the profession, and still more of the public, for his question on this subject in the House of Commons. The reply of Mr. Chaplin is very satisfactory and shows that he at least has not been an unmindful spectator of the financial irregularities which have been brought to light partially in the Brook Hospital case, but which are perhaps not confined to that case. It would be lamentable indeed if the Local Government Board could be supposed to be careless in this matter in which it has such enormous responsibilities. Mr. Chaplin rather invited Dr. Farquharson to move for further returns which doubtless Dr. Farquharson will ask for. The public is almost helpless in such matters. It knows nothing of the cost of hospitals or of their administration. There is nothing in such a question to excite the interest of parties or of party leaders who are apt to spend public money recklessly. But unless local government and those who administer it are to be discredited we must take it out of the hands of architects and those who see nothing in it so much as a boundless and unchecked means of spending public money.

HOT WEATHER DANGERS.

"TO-DAY is the hottest day experienced in London this year, the thermometer registering 86° F. in the shade, and numerous cases of sunstroke are reported." Such was the announcement made in several evening papers on Monday last, the 18th. In the papers of the next morning (the 19th) it was announced that a serious explosion had occurred at the Earl's-court Exhibition on the afternoon of the 18th in connexion with a magazine in which various explosives used in the miniature naval battle were stored. There can be little question, we think, that the first observation throws light on the occurrence of the accident in which unfortunately life was lost and several employés were injured. It is certain that amongst the stored explosives would be some containing nitro-compounds of the class of nitro-glycerine. Under the influence of higher temperatures the fluidity of nitro-glycerine would be very materially increased and nitro-glycerine is infinitely more dangerous in the liquid form than in the solid. Dynamite is a porous earth containing nitro-glycerine which affords a comparatively safe way of carrying and storing the explosive, but when exposed to variations of temperature in the upward direction the oil would probably exude and become dangerous. Thus the slow exudation of the nitro-glycerine is a serious danger because it tends to substitute pure nitro-glycerine for a substance which is but little sensitive to shocks or friction, while the former is, on the

Digitized by Google

contrary, extremely sensitive. Direct sunlight is also bad for nitro-compounds as it often leads to their chemical decomposition and to spontaneous explosion. The places or magazines where explosives are stored should therefore be kept cool and in a sheltered spot. It would not be surprising to learn that this was not the case in the unfortunate disaster which happened at Earl's Court. An official inquiry, however, will probably clear up this point.

"THIS HILL IS DANGEROUS."

A STORY of distinctly emerald tinge is related in last week's *Bicycling News*. An English cyclist touring in Ireland came upon a steep descent, but looked in vain for the familiar notice-board indicating danger. Dismounting he wheeled his machine down and right at the bottom of the hill he discovered the missing notice-board, "This Hill is Dangerous to Cyclists." We are not sure whether the man who erected the notice-board is a humourist or some voluntary Ixion with a dilated heart, the penalty of a disinclination to leave his wheel and walk up-hill. It is perhaps a debateable question whether for the benefit of middle-aged cyclists all danger boards should not be placed at the bottom of the hills to which they refer. No doubt there would be more broken necks, but on the other hand there might be fewer over-stretched hearts.

THE LATE GEORGE VERNON BLUNT, M.D. ABERD.

THE will of the late Dr. George Vernon Blunt has recently been proved in the Birmingham district registry at the sum of £43,085, which is considerably more than a medical man, as a rule, has it in his power to leave. The estate is to be kept intact for a period of twenty-one years and certain annuities are to be paid out of the income while the surplus income is to accumulate. After the annuities are satisfied the estate is to be divided, according to the *Birmingham Gazette*, as follows:—

	£
The Blue Coat School, Birmingham	3000
The General Institution for the Blind, Carpenter-road, Birmingham	1000
The Royal Institution for Deaf and Dumb Children, Church-road, Birmingham	1000
The Gordon Boys' Home, Cobham	5000
Mr. Barnardo's Homes, Stepney	6000
The Royal Orphan Asylum for Orphans of Soldiers, Sailors, and Marines at Devonport	5000
The Royal Cambridge Asylum for Soldiers' Widows, Kingston-on-Thames	6000
The Free Cancer Hospital, Brompton, to found two beds	3000
The Royal National Lifeboat Institution, for building and equipping two lifeboats and stations	6000
And the residue to the Shipwrecked Fishermen and Mariners' Royal Benevolent Society.	

The selection of charities is, we think, very catholic and one with which no one will quarrel, for there is hardly any form of infirmity or distress which does not benefit by the bequests.

ABSCESS OF THE BRAIN.

A CASE illustrating the difficulties and uncertainties attending upon operations for cerebral abscess was described at the December meeting of the New York Neurological Society by Dr. F. Peterson. The patient had attempted suicide and wounded his head with a rusty spike and had sustained a compound depressed fracture in the occipital region near the middle line on the right side. He was trephined and the depressed bone was removed. The dura mater seemed to have escaped injury and was left untouched. The wound became infected, but no symptoms appeared for two weeks after the operation. He then gradually developed, in the course of twenty-four hours, left-sided paralysis with hemianæsthesia. The mental condition was clear and there was no aphasia. The temporal half of the field of vision of the left eye was lost; the right is said to have seemed normal. The fundus was slightly clouded. It was thought that there was an abscess deeply situated in the region of the posterior limb of the internal capsule and two days later an exploring needle was introduced and an abscess was evacuated and drained. The anæsthesia disappeared and the patient moved his left hand, but a few days later he suddenly became worse and died. An abscess of the size of a hen's egg was found deeply situated in the right hemisphere, but from the report it is not clear whether this was another abscess or merely a reaccumulation in the cavity which had been emptied. One curious and interesting symptom was the occurrence of blindness of the temporal half of the visual field of the left eye without any apparent involvement of the visual field of the right eye, and if the abscess found post mortem was another collection of pus, the case illustrates the fact that intra-cranial abscess is not infrequently multiple.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

THE forty-fifth annual report of the Royal Medical Benevolent College, which provides pensions for aged medical men and the widows of medical men in reduced circumstances, with a school open to all classes but offering special advantages to the sons of medical men, 50 of whom are Foundation scholars, has recently been issued. Though the year has been one of great anxiety in consequence of large but necessary expenses there is a small credit balance. This is satisfactory, but funds are urgently needed and unless increased support is forthcoming the College will be seriously impeded in both sides of its work. It should be borne in mind that "it is not only a benevolent society giving help to the aged and the disabled, and doing inestimable good to the children of those medical men who, from death or other misfortunes, have been unable to provide for their families but it is also a great educational institution, by which the whole profession is benefited; and as such it is entitled to the support, in the first place of medical men, and afterwards of all those who are sensible of their obligations to the medical profession." It is also important to notice that while the expenditure of the benevolent side of the institution is considerably over £6000 a year, the amount received from annual subscriptions is under £3500. The office of the College is at 37, Soho-square, London, W.

A MEDICAL CLEARING-HOUSE.

THE *Manchester City News* of July 16th publishes an article from a correspondent dealing with a project well worthy of consideration by any town which is not so unwieldy in size as London. The writer recalls attention to the fact that many of the Manchester hospitals have their out-patient departments separated from the main building by a distance of, in one instance at least, some miles. Manchester is about to build a new infirmary and the scheme suggested is one to run concurrently with the building scheme. The writer proposes to "erect a building in the centre of the city, on a site to be determined later, which will accommodate all the out-departments of the various hospitals and infirmaries. Each of these sections would be under the care of the same distinguished specialists who are now on the staffs of the various special hospitals, and a small number of beds should be provided for emergency cases. It would, in short, be made the medical clearing-house of Manchester." We cannot but think that this scheme offers certain advantages over the system at present existing in Manchester. For a hospital to have its wards separated from its out-patient department by a distance of over a mile involves an enormous waste of energy of various kinds, principally of labour and money. Another great advantage, as the correspondent of the *Manchester City News* points out, would be the remarkable facilities for teaching

Digitized by Google

which such a building would afford, for the mass of clinical material gathered together would be enormous. In the case of London we imagine that such a scheme is not necessary, for in no one of the hospitals so far as we know is the out-patient department distant from the main body more than a few yards; but even were the conditions in London on a par with those of Manchester as regards this point the distances in London are far too great to enable the plan to succeed, and no one building could ever provide for the crowds of out-patients who flock to a London hospital. However, it may be feasible in Manchester, and at any rate the proposal is worth serious consideration.

HEROISM WITH RISK.

THE gallant action of Surgeon-Lieutenant J. H. Hugo of the Malakand Field Force will be fresh in our readers' memory, but none the less we may recapitulate the main facts. A brother officer had been hit by a bullet which cut the axillary artery. Surgeon-Lieutenant Hugo came to his aid and having recognised the injury by the light of a match compressed the vessel between his finger and thumb and held on to it under fire for three hours. When the enemy broke into the camp Surgeon-Lieutenant Hugo picked up the patient and carried him into a place of safety. For this act of bravery Surgeon-Lieutenant Hugo has, we are glad to say, been awarded the Distinguished Service Order. It is no light task even in a quiet room to hold on to an artery for three hours, or even for one, knowing that a man's life depends on the grasp not slipping. To do so with bullets flying all round adds an element calculated to make the task infinitely heavier. The Royal Army Medical Corps and the whole profession may well be proud of Lieutenant Hugo (to give him his present title).

DR. WATT BLACK, after a service of close on 30 years, has resigned the appointment of Obstetric Physician to Charing-cross Hospital and the Council have appointed Dr. Amand Routh to succeed him.

SIR WILLIAM HENRY BROADBENT, Bart., has been appointed one of Her Majesty's Physicians Extraordinary in the room of the late Sir Richard Quain.

THE ACCIDENT TO THE PRINCE OF WALES.

THE profession will have heard with regret that His Royal Highness, during his recent visit to Baron Ferdinand de Rothschild, in descending the staircase at the Manor House, Waddesdon, slipped and fractured his patella. It was at first thought that the injury was less serious, but on the Prince reaching London and being examined by Sir William Mac Cormac and Sir Francis Laking it was found that a fracture had unfortunately occurred. The leg affected is the same one in which many years ago after his severe attack of typhoid fever phlebitis ensued. The accident, as our readers are aware, though troublesome and somewhat tedious in its cure, is fortunately not in any way dangerous to life. It may be interesting to recall its mode of causation. In walking along, sometimes in ascending or descending stairs, the foot slips and the weight of the body forcibly bends the knee; to prevent a fall the quadriceps extensor muscle in the front of the thigh makes a sudden and violent contraction; the strain on the patella, resting as it does on the condyles of the femur, is too great and the bone breaks through the excessive energy of the muscular contraction. Immediately the patella gives way the continued action of the muscle draws the upper fragment away from the lower and an obvious gap is felt between the two pieces. All power to extend the leg is at once lost and the only result of attempts to do so is to increase the distance between the fragments. The fracture always opens into the knee-joint and pain and swelling soon follow from the exudation into the articulation. The difficulties in the way of treatment are many and various and some permanent weakness of the injured joint is not unlikely to result. With care, however, and with time much may be done to ensure a firm union; but whatever treatment be adopted the sufferer must exercise patience if he is desirous of having a limb as strong as before the accident occurred. The fracture is certainly more common in men than in women, probably because it is produced by muscular action; it is almost unknown in children; and it is most frequently met with in the middle period of life, rarely indeed being seen in old age.

The treatment in the Prince of Wales's case will doubtless be the one usually adopted, that is, confidence will be placed in splinting, bandaging, &c.—to secure union in a good position. We understand that the alternative question of operation—i.e., of opening the knee-joint and wiring together the fragments of the patella—has had the fullest and most anxious consideration by the medical attendants, who, after careful weighing of all the circumstances of the case, have decided against it. Lord Lister, who was subsequently called in and whose authority in such matters is indisputable, fully endorsed this view of the matter and the favourable position of the fractured ends of the bone as disclosed on Thursday morning goes far to justify the decision. On that morning at a consultation held at Marlborough House between Lord Lister, Sir William Mac Cormac, Sir Thomas Smith, and Sir Francis Laking a very careful examination was made of the precise state of the fracture. The treatment carried out so far was found to have greatly improved the position of the fragments at the seat of the fracture, and the progress made is all that can be desired in the time which has elapsed since the injury. Lord Lister expressed himself as very much pleased with the progress made and is perfectly satisfied that the right course of treatment is being adopted.

Sir William Mac Cormac has handed us the following report for publication:—

"In consequence of the wide-spread interest taken and the sympathy shown for H.R.H. the Prince of Wales in his recent unfortunate mishap, His Royal Highness, with characteristic consideration for the wishes of those who desire authentic information as to the nature of the injury, has sanctioned the following statement: On Monday morning, July 18th, while coming down the spiral staircase at Waddesdon Manor he missed his footing and in the sudden severe effort made to save himself from falling sustained a fracture of the left patella. On examination it was found that the line of fracture was nearly transverse and close to the upper margin of the patella. About one fifth of the bone, somewhat crescentic in shape, was torn away along with the tendinous insertion of the quadriceps extensor and the gap between the fragments amounted to a little more than 2 in. The joint was distended with blood. Means were adopted to immobilise the limb, bring down the upper fragment, and to prevent tilting. This has proved so far successful that upon examination to-day (Thursday) it was found that the interval between the fragments was greatly diminished, not being now more than a quarter of an inch, and the effusion in the joint is lessened considerably. The condition of the illustrious patient is in other respects most satisfactory, and he is bearing the enforced restraint with exemplary patience and good temper."

His Royal Highness will have the sympathy of the profession during the necessary but irksome period of rest to which he will be subjected and their earnest wishes for his speedy recovery.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE thirtieth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, July 18th. With the exception of the Right Hon. William Mellor all the Commissioners were present. The first part of the sitting was occupied in taking the evidence of Mr. Henry Weeden, vice-chairman of the Ilford Urban District Council. Mr. Frederick George Banbury, M.P., a trustee and manager of the Stock Exchange, then explained a scheme of purchase of the London water companies' undertakings which in his opinion would not increase the rates now paid by consumers and would give the consumer free of cost any possible future increase of profit. Mr. Allen Stoneham, the auditor appointed by the Local Government Board to examine the water companies' accounts, next gave evidence. The latter part of the sitting was occupied by the examination of Mr. Reginald E. Middleton, who gave evidence on behalf of some of the water companies.

Mr. WEEDEN, in answer to the CHAIRMAN, said that the inhabitants in the area of the Ilford Urban District Council obtained their water-supply partly from the East London Waterworks Company and partly from the South Essex Waterworks Company. The district was divided into two distinct areas and there was no competition between the companies. The witness said that the council which he represented were satisfied with the charges made by the East London Waterworks Company and with the quality and the quantity of the water they supplied. The charges made by the South Essex Company were higher than those made by the East London Waterworks Company and the people were not so well satisfied with the quantity and quality of the water supplied to them by the provincial company. There were, in fact, frequent and bitter complaints made with regard to the charges levied by the company. The council which he represented wished to have power either to buy up those parts of the East London Company's works which were in their district and to compete with the South Essex Company, or if the London County Council were authorised by Parliament to buy up the East London Waterworks Company's undertakings they thought that they should be supplied with water in bulk in sufficient quantity to enable them to distribute it in competition with the South Essex Water Company.

In answer to the CHAIRMAN the witness said that applications had been made to the East London Company to supply that part of their district which is now in the area of the South Essex Company and the East London Company had declined to do so.

Mr. DE BOCK PORTER suggested that possibly the East London Waterworks Company were bound by an agreement with the South Essex Company not to supply any water in their district.

In answer to the CHAIRMAN the witness said that no agreement had been made with the London County Council that the Ilford district should have a large increase of water should the East London Company's undertakings be bought by that body.

The CHAIRMAN, referring to the Metropolitan Water Act of 1897, suggested that it applied to the whole of the authorised area of the East London Waterworks Company, and that under this Act the people of Ilford could obtain a constant supply of water, which they have not at present.

Mr. FREDERICK GEORGE BANBURY, M.P., in answer to the CHAIRMAN, said that he was a trustee and manager of the London Stock Exchange. He suggested that in case of purchase of the metropolitan water companies' undertakings the scheme which he submitted would not increase the rates now paid by the consumers and would give to the consumers any increase of profits which might accrue to them under the new management. He suggested that Parliament should create a small statutory central body and that this body should be authorised to create a 3 per cent. perpetual water stock secured on the water rents. The new stock should be made transferable at the Bank of England and trustees should be entitled to invest in it. Each shareholder and debenture-holder in the undertakings of the present metropolitan water companies should receive a sufficient amount of the new water stock to yield to him the same amount of dividend that he is now receiving. One advantage of this scheme was that the purchasing authority would not require to raise any more money than the companies are now raising for new works, if the undertakings were, under the new management, carried on as economically as they are by the present companies. Under the proposed arrangement also all saving in expenses which might arise from the amalgamation of the eight companies would accrue to the water consumers. If it should happen that the profits of the amalgamated undertakings continued to increase as those of the water companies had done in the past, these profits would go to the consumers who would have paid nothing for them. If, again, the profits remained stationary the water consumers would be in the same position in which they are at the present time. Under his scheme nothing was to be paid to the water companies' shareholders for these compulsory changes. In the opinion of the witness this arrangement would be fair to the shareholders as they would gain by the increased value which would be given to their stock by the consolidation of the undertakings and by the fact that trustees were allowed to invest in the new water stock. The advantage of this scheme to the consumer was that the companies' undertakings would be purchased for him for the price he is now paying and he would obtain the advantage of any saving which might be made under the new management and any future increase in revenue which might accrue. The newly constituted water board should receive power to raise money for extending the water undertakings as London increased and judging from past experience this extension would be a source of profit. The companies had during the last twenty years considerably increased their capital and their dividends had also increased considerably. In the opinion of the witness purchase on the basis of the dividend now paid was the only satisfactory method. For some years past each company has been compelled to have its accounts examined by a Government auditor, so that no "tampering with" the dividend was possible, whereas, on the other hand, it is impossible to ascertain the true capital value of such an undertaking. At the present time on the Stock Exchange the market for water companies' stock is small and is not a true criterion of the real value of the stock. The market value of a water company's stock can be easily manipulated. No manipulation is possible in the case of a water company's dividend. Under the scheme which he suggested no new capital would have to be raised by the London ratepayers. This was a very great advantage, for the raising of thirty or forty millions would necessarily affect the money market. If the London County Council were to attempt to raise so large a sum they would not be able to obtain it on terms so advantageous as those on which they were able to raise smaller sums. The scheme he suggested would also supply a growing and long felt want—namely, good trustee securities. With regard to the composition of the new water board—the statutory body which he suggested should be formed to carry out the purchases—the witness suggested that the body should be selected somewhat on the same lines as the Council of India, and it should consist of nine or ten paid members who should be appointed because of their fitness to undertake the management and administration of water supplies.

In answer to the CHAIRMAN the witness said that the new authority should have power to arrange as to what amount of water rent should be paid by the consumers.

In answer to Mr. CRIPPS, Q.C., the witness said that he thought the shareholders of the water companies would be very silly if they did not accept the scheme which he had submitted. It would be a good bargain for them. In the case of purchase on the lines he suggested it was true that a good company would obtain less advantage than a bad company if there were such a thing. In the case, for example, of the West Middlesex Waterworks Company the full authorised amount of water rent was not charged because the company was able to pay full dividends without doing so. Still the shareholders of that company would gain by the proposed alteration because they would have a more marketable stock, and one which could be purchased by trustees. Those companies which were on a less satisfactory financial basis would doubtless gain more than the West Middlesex Company would do by the changes. The witness, however, thought that purchase by arbitration would not be a good thing because it would add materially to the cost of transfer. Although nothing was given under

Digitized by Google

his scheme by way of compensation for compulsory purchase the present holders of water companies' stock would gain largely in capital value. At the present time trustee securities were very scarce.

In answer to Sir JOHN DORINGTON the witness said that a 3 per cent. trustee stock at the present time was worth about £115. He thought, however, 3 per cent. was the best amount to arrange for the new water stockholders to receive. Water consumers would obtain the future profits of the undertakings. The witness was opposed to the purchase of the water companies' undertakings by the London County Council. "The City had not much faith in the business capacities of the London County Council."

In answer to Mr. ROBERT LEWIS, who asked whether it would not be possible to make the stock terminable by periodical drawings, the witness said that such an arrangement would not do at all. It was essential that the new water stock should be a "trustee stock."

In answer to the CHAIRMAN the witness said that he thought that the shareholders of the London water companies would consent to the scheme he had suggested, that it would be a great advantage to the shareholders, and as both the parties chiefly interested would profit it was not necessary to pay any attention to the wishes of the London County Council. People objected to purchase by the London County Council, but they would not object to the management being in the hands of a central board.

In answer to Mr. DE BOCK PORTER the witness pointed out that the reason why the present shareholders of the companies' undertakings would benefit was that at the present time there was very little market in the water stocks. Buying water stocks was a matter of negotiation and a jobber would not "make a price." The consolidated water stocks would be readily marketable.

With regard to the proposed new water board Sir JOHN DORINGTON asked the witness whether he considered that a body of experts would manage the business better than an amateur body. The witness asked Sir John Dorington whether that was not his experience and admitted that for his own part he had found that things which required special knowledge were not best managed by amateurs. The witness thought that local authorities should retain the powers which they at present possess with regard to control of the water-supply.

The CHAIRMAN pointed out that in the case of purchase by the London County Council they had been distinctly told by the chairman of the water committee of that body that "the representatives of the people" would not require any control whatever.

In answer to the CHAIRMAN the witness said that he did not believe that there was any "cry" in favour of purchase of the water companies by municipal authorities. Lord Farrer, formerly one of the chief supporters of that policy, had changed his mind on the subject.

In answer to Mr. POPE, Q.C., the witness pointed out that the present owners of water stock would gain an enormous advantage by having a free market in their stocks and from the fact that they would become trustee stocks, a thing which perhaps "the lay mind," if he might say so, might fail to grasp at once.

In answer to Mr. CRIPPS, the Parliamentary agent of the London County Council, the witness said that he was not a holder of any water stocks and that the scheme which he had submitted was his own. The cause of one of the East London water famines was due to the opposition of the London County Council to the East London Waterworks Company's Bill for the enlarging of the reservoirs. This statement Mr. CRIPPS denied. Mr. PEMBER, Q.C., loudly re-asserted it and the CHAIRMAN said the matter did not concern the Commissioners and the Commission could not be made a draught house for the dispute.

Mr. ALLEN STONEHAM, the auditor appointed by the Local Government Board under the Metropolis Water Act of 1871 to audit the accounts of the metropolitan water companies, explained the system on which he examined the accounts. In answer to the CHAIRMAN the witness explained that according to the Act of Parliament under which he worked the accounts of the companies were examined from the years 1864 or 1869. When he took over the audit he had necessarily to accept the capital account as given by the metropolitan water companies. In some cases doubtless the capital represented obsolete works. He had been forced on more than one occasion to go to arbitration with regard to the accounts submitted by the metropolitan water companies. On one occasion, for example, there was a question as to the place in which the amount received for the sale of property belonging to the New River Company should be put, whether it should be considered as capital or as interest. In this case the decision given by the present Lord Chancellor was in favour of the company. The witness pointed out that he was not an engineer, that he had no right to visit the companies' properties, and that of course he could not tell whether the engines were worn out or not.

In answer to Mr. DE BOCK PORTER the witness said that the companies did not write off anything for depreciation.

In answer to the CHAIRMAN the witness said that with regard to the amount paid for engines he had, of course, to trust that the directors paid the right amount and that the sums paid were correctly given in the accounts submitted to him. In case the witness required counsel's opinion he had to pay for it himself. He had applied on one occasion to the Board of Trade for expenses which he had paid out of his own pocket and the Board declined to pay those expenses. In one case in which he felt compelled to go to arbitration Sir Henry James, who was the arbitrator, had "acted as counsel" for him. In that case Sir Henry James was arbitrator and "counsel"—that is to say, he told the witness he would do what he could to assist him.

The CHAIRMAN asked whether in this case Sir Henry James was arguing the case "to himself." The witness said that this was the fact and that the Solicitor-General was against him. The Act under which he was appointed made no provision for any legal expenses to be paid by the witness.

In answer to Mr. PEMBER, Q.C., the witness said that although the money paid to him by way of remuneration for his services was as a matter of fact found by the companies it was collected, apportioned, and paid by the Local Government Board.

In reply to Mr. CRIPPS, the Parliamentary agent of the London County Council, the witness said that the West Middlesex Company got rid of some of their surplus profits by giving gratuities to clerks and officials. With regard to the general question of what was capital expenditure, when the witness objected to any particular item occasionally the companies gave way and occasionally he gave way.

Mr. REGINALD E. MIDDLETON, who gave evidence on behalf of some of the metropolitan water companies, said he was a civil engineer, a Member of the Institution of Civil

Estimate of the cost for the construction of five reservoirs to hold a total quantity of 18,000 million gallons and to afford a supply of 123½ million gallons a day.

	£	£

Engineers, of the Institution of Mechanical Engineers, Fellow of the Surveyors' Institute, Member of the Sanitary Institute, and Fellow of the Royal Meteorological Society. He was Assistant Commissioner to the Royal Commission of which Lord Balfour was chairman. The witness handed in a printed statement of considerable length some of which bore upon the evidence which was given by Sir Alexander Binnie. The tables were, however, not drawn up on exactly the same lines and the CHAIRMAN remarked that it seemed to be a pleasure to scientific gentlemen to introduce changes. These changes did not facilitate a comparison between the statements which had been put in by Sir Alexander Binnie and those of the present witness, who was asked to submit a table at the next meeting which could be more easily compared with those given by Sir Alexander Binnie. There were, however, two tables which the Chairman considered of sufficient importance to go on the notes. Of these tables one referred to the Thames storage reservoirs and the other to the cost of the work necessary for bringing a supply of water from Wales. These tables should be compared with those given by Sir Alexander Binnie which have already been published in THE LANCET.[1]

The next sitting of the Royal Commissioners will be held at the Guildhall, Westminster, on Monday next, July 25th, at 12 midday. It is hoped that after Monday next there will be an adjournment until some date, not yet fixed, in November.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

QUARTERLY MEETING OF COUNCIL.

A QUARTERLY MEETING of the Council was held on July 14th, the President, Sir WILLIAM MAC CORMAC, Bart., being in the chair.

The PRESIDENT reported the result of the election of members of Council, as published in THE LANCET of July 9th, p. 114, and Mr. Richardson Cross, Mr. Morris, and Mr. Langton were introduced, made the declaration in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council.

The SECRETARY reported the death, at the age of eighty-one years, of Mr. Henry Lee, a past-member of the Council, and the Council recorded their deep regret at the death of Mr. Henry Lee whom they greatly esteemed both as a colleague and as a member of the profession and expressed their very sincere sympathy with his widow and family in their bereavement.

The Council approved of a sum of money being expended upon a series of drawings illustrating the pathogenic bacteria of man.

A report of the Committee of Management was approved: it was to the effect that, as already approved by the Royal College of Physicians of London, candidates for the second examination should be required to dissect for twelve months after having received the instruction necessary for admission to Parts I. and III. of the first examination.

The Council (on the recommendation of the Nomination Committee) made the following appointments:—

Hunterian Professors: Mr. Leonard Erskine Hill (subject: Researches on the Influence of Gravity on the Circulation); Mr. Frederick Gymer Parsons (subject: Joints of Mammals contrasted with those of Man); and Mr. Charles Stewart (subject not determined). *Arris and Gale Lecturer:* Mr. Berkeley G. A. Moynihan (subject: The Anatomy and Surgery of the Peritoneal Fossæ). *Erasmus Wilson Lecturer:* Dr. Thomas Grigor Brodie (subject: The Chemical Pathology of some Infective Diseases).

Mr. Rickman J. Godlee was re-elected a member of the Court of Examiners and Mr. J. Howard Mummery was elected a member of the Board of Examiners in Dental Surgery.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at their late session, and the best thanks of the Council were given to Mr. Bryant for his services as the representative of the College on the General Medical Council.

A letter was read from the Metropolitan Counties Branch of the British Medical Association thanking the Council for allowing the branch to hold a conversazione at the College in June last.

Mr. Bryant was nominated as representative of the College on the Council of the Queen Victoria's Jubilee Institute for Nurses.

The PRESIDENT reported that the required quorum was not present on July 7th when a meeting of Fellows had been called and therefore no meeting was held.

Mr. Thomas Cooke's school was recognised for the ensuing year.

As already reported in THE LANCET, Sir William Mac Cormac, Bart., was re-elected President and Mr. T. Pickering Pick and Mr. Howard Marsh were appointed Vice-presidents. Mr. S. G. Shattock was re-elected pathological curator.

The next meeting of the Council will be held on Tuesday, Aug. 2nd.

ADDITIONS TO THE MUSEUM.

Every year for two or three days in the week in which the election to the Council takes place there is an exhibition of all the specimens which have been added to the Museum during the preceding year.

The new specimens are far too numerous to be mentioned in detail, but an account must be given of those of the greatest interest and importance. Mr. Breward Neal has presented the base of a skull from a case of acromegaly; it shows a greatly enlarged pituitary body. Dr. A. E. Lloyd has given some specimens from a case of diffuse congenital angeioma of the leg; many phleboliths are shown in the dilated deep veins and the tibia and fibula have had an irregular deposit on the surface of new periosteal bone. A specimen of the tongue and larynx from a case of leprosy shows well the great amount of deformity which may occur in these organs in this disease. Almost all the specimens which illustrated Mr. Percy Furnivall's Jacksonian Prize Essay have been added to the Museum; they are twenty-three in number and consist of morbid growths from the stomach and intestines and one specimen shows a section of intestine with a Murphy's button *in situ;* this is intended to illustrate the manner in which the button unites two pieces of bowel. Professor Rose Bradford has presented a specimen which shows the atrophy of the kidney following ligature of the ureter when the dilated pelvis is subsequently drained. Mr. Pearce Gould has given an example of a horseshoe kidney affected with carcinoma. A series of six specimens of molluscum contagiosum on the heads of birds shows well the prevalence of this disease and the fact that two of the specimens (North American bunting sparrows) were mates is much in favour of the contagious character of the condition. The first ovarian cyst removed by Sir Spencer Wells (in 1858) is amongst the additions. Marked retroflexion of the uterus in a monkey is shown in a specimen presented by Dr. W. K. Sibley. Mr. J. Tweedy and Mr. Devereux Marshall have given seven preparations mounted in glycerine jelly illustrating injuries and diseases of the eye.

Laennec's stethoscope (a somewhat ponderous instrument) and the first subcutaneous osteotomy saws used by Mr. William Adams were also on view.

The drawings and photographs were very good and especially must be mentioned one showing hypertrophy of the breasts presented by Mr. H. H. Clutton, and a skiagram showing phleboliths in the case of diffuse angeioma already mentioned.

Mr. Shattock, the pathological curator, has commenced to prepare a series of specimens illustrating the naked-eye characters of cultures of the chief bacteria causing disease in the human subject; these have been preserved by formalin and are to be accompanied by drawings of the microscopic appearances of the micro-organisms. A series of specimens almost equally useful illustrates the effects in animals of inoculation by pathogenic organisms; for instance, one specimen was part of the back of a rabbit showing an abscess due to the intramuscular injection of a broth culture of staphylococcus pyogenes aureus. The additions to the physiological series are even more numerous. A large number of specimens illustrate the various forms of flexible bands intended for union and support. Many specimens show the variations which occur in the muscular systems in animals; as an instance may be mentioned a specimen illustrating the fact that in a setter the soleus muscle is absent. The separation of the two constituent portions of the suprarenal bodies is shown in a skate (Raia clavata), in which are (*a*) a series of small-paired bodies on

[1] THE LANCET, June 11th, 1898, p. 1644.

Digitized by Google

the costal arteries and connected with the sympathetic nervous system, and corresponding to the medulla; and (*b*) an interrenal U-shaped body which corresponds to the cortex of the suprarenal bodies of higher vertebrates.

The exquisite dissections, for which the Museum is unrivalled, are on this occasion numerous, and especially may be mentioned dissections showing the sensory and ampullary canals of the skin; these are intended to secrete a lubricating mucus, but from the presence in them of "hair cells" like those in the olfactory mucous membrane and the ampullæ of the semicircular canals, they are thought to be also organs of sense.

Symbiosis is illustrated by some ants (Coractus intrudens) and portions of the stem of a plant in which they live, and parasitism is exemplified by a dodder (Cuscuta epithymum), which lives on a gorse (Ulex europæus); as the dodder does not contain chlorophyll it is dependent on its host whom it pierces by special processes. The dissections illustrating human anatomy are numerous.

There is only one thing to be regretted about this exhibition and that is the fact that it was open for only two days. We think that if it were possible it would be well to have it open for at least a week.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6411 births and 3159 deaths were registered during the week ending July 16th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 15·1 to 14·7 per 1000, was last week again 14·7. In London the rate was 14·1 per 1000, while it averaged 15·1 in the thirty-two provincial towns. The lowest death-rates in these towns were 8·7 in Portsmouth, 9·0 in Blackburn, 9·2 in Croydon, and 9·5 in Derby; the highest rates were 19·0 in Manchester, 19·3 in Salford, 22·6 in Bolton, and 22·9 in Newcastle-upon-Tyne. The 3159 deaths in these towns included 378 which were referred to the principal zymotic diseases, against 342 and 330 in the two preceding weeks; of these, 122 resulted from diarrhœa, 83 from whooping-cough, 79 from measles, 54 from diphtheria, 24 from scarlet fever, and 16 from "fever" (principally enteric). No fatal case of any of these diseases occurred last week in Croydon or in Blackburn; in the other towns they caused the lowest death-rates in Sunderland and Brighton, and the highest rates in Plymouth, Salford, Birkenhead, Gateshead, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Plymouth, Norwich, Newcastle-upon-Tyne, and Gateshead; and from whooping-cough in West Ham, Salford, and Gateshead. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 54 deaths from diphtheria included 39 in London, 4 in Cardiff, and 3 in Leeds. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2314, against 2238, 2205, and 2250 on the three preceding Saturdays; 265 new cases were admitted during the week, against 231, 204, and 237 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 162 and 160 in the two preceding weeks, rose again to 175 last week, but were 9 below the corrected average. The causes of 29, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Manchester, Leeds, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·1 and 20·0 per 1000 in the two preceding weeks, further declined to 18·5 during the week ending July 16th, but exceeded by 3·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·0 in Aberdeen and 17·7 in Dundee to 23·7 in Greenock and 23·8 in Perth. The 559 deaths in these towns included 26 which were referred to whooping-cough, 26 to diarrhœa, 23 to measles, 9 to scarlet fever, 5 to "fever" (principally enteric), and 4 to diphtheria. In all, 93 deaths resulted from these principal zymotic diseases, against 119 and 96 in the two preceding weeks. These 93 deaths were equal to an annual rate of 3·1 per 1000, which was 1·3 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 35 and 21 in the two preceding weeks, rose again to 26 last week, of which 18 occurred in Glasgow, and 4 in Paisley. The 26 deaths from diarrhœa were within one of the number in the preceding week, and included 16 in Glasgow. The fatal cases of measles, which had been 41 and 36 in the two preceding weeks, further declined to 23 last week, of which 10 occurred in Glasgow, 4 in Edinburgh, and 4 in Dundee. The 9 deaths referred to scarlet fever showed a slight further increase upon recent weekly numbers and included 4 in Edinburgh, 2 in Glasgow, and 2 in Dundee. Of the 5 fatal cases of "fever" 4 were recorded in Glasgow, and the 4 deaths from diphtheria included 2 in Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 101 and 106 in the two preceding weeks, declined to 76 last week, but slightly exceeded the number in the corresponding period of last year. The causes of 35, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 22·8 to 20·3 per 1000, further fell to 18·5 during the week ending July 16th, a lower rate than has been recorded in any week since September, 1896. During the past four weeks the death-rate in the city has averaged 20·9 per 1000, the rate during the same period being 14·4 in London and 19·5 in Edinburgh. The 124 deaths registered in Dublin during the week under notice showed a decline of 12 from the number in the preceding week, and included 3 which were referred to the principal zymotic diseases, against 11 and 6 in the two preceding weeks; of these, 1 resulted from scarlet fever, 1 from whooping-cough, and 1 from diarrhœa, but not one either from small-pox, measles, diphtheria, or "fever." These 3 deaths were equal to an annual rate of 0·4 per 1000, a lower rate than has been recorded in any week since February, 1896. The zymotic death-rate last week was equal to 1·9 per 1000 both in London and in Edinburgh. The 124 deaths in Dublin last week included 16 of children under one year of age, and 27 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Six inquest cases and 4 deaths from violence were registered; and 49, or more than a third, of the deaths occurred in public institutions. The causes of 5, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NAVAL MEDICAL SERVICE.

THE following appointments of Staff-Surgeons are announced:—Ernest E. Bray to the *President*, for the Royal Victoria Yard, Deptford, and George Welch to the *Boscawen*, for Portland Sick Quarters.

ROYAL ARMY MEDICAL CORPS.

Major W. E. Berryman has been appointed Embarking Medical Officer, Southern District, as a temporary measure, in addition to his other duties. Major F. H. Treherne has assumed charge of the Station Hospital, Brighton. A special Army Order has been issued stating that permission will be given to non-commissioned officers and men belonging to the Reserve of the Royal Army Medical Corps (sections B and C) to rejoin the colours, according to the terms of their service, subject to certain conditions. Major James E. Nicholson retires from the service receiving a gratuity. Surgeon-General W. Taylor has been appointed Principal Medical Officer on the staff of Major-General W. F. Gatacre, C.B., in the forthcoming expedition to Khartoum.

The Khedive of Egypt has decided to bestow the Order of

Digitized by Google

the Osmanieh on Captain Penton, who was attached to the Soudan Expedition. Lieutenant Hugo, who attended a dangerously wounded brother officer for three hours under fire, holding his bleeding artery and finally bearing him to a place of safety, has been rewarded with the decoration of the Distinguished Service Order. Lieutenant-Colonel G. H. Le Mottée, who has been promoted to brigade rank, took part in the Boer War of 1881.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain Grayfoot have been placed at the disposal of the Military Department. Surgeon-Lieutenant-Colonel Dane is promoted to be Brigade-Surgeon-Lieutenant-Colonel, vice Brigade-Surgeon-Lieutenant-Colonel Arnott, retired. Surgeon-Lieutenant Powell (Burmah Valley Light Horse Volunteer Corps) has been appointed Surgeon-Captain. Surgeon-Lieutenant-Colonel Pemberton (Malabar Volunteer Rifles) has resigned his commission. Surgeon-Lieutenant Watson (6th Infantry, Hyderabad Contingent) has been appointed to the Officiating Medical Charge of the Regiment, vice Surgeon-Lieutenant-Colonel Swaine, appointed to officiate as Principal Medical Officer, Hyderabad Contingent. Surgeon-Captain Buchanan has been appointed Temporary Superintendent of the Central Jail, Dacca. Surgeon-Captain Gwyther has been appointed to be Inspecting Medical Officer at Chausa Station on the East Indian Railway. Surgeon-Captain Deare has been appointed to be Civil Surgeon of Nadia. Surgeon-Captain Oldham has been appointed to be Civil Surgeon of Backerganj. Surgeon-Major Walsh has been appointed to act as temporary Civil Surgeon of Murshidabad. Surgeon-Lieutenant-Colonel McConaghey, Civil Surgeon, Lucknow, has been appointed to hold Visiting Medical Charge of Rae Bareli in addition to his own duties. Surgeon-Captain Crawford, Civil Surgeon, has been transferred from Muttra to Lucknow. Surgeon-Captain Morton (Madras) has been transferred to the half-pay list. The following officers have retired from the service: Brigade-Surgeon-Lieutenant-Colonel Cunningham C.I.E. (Bengal), Surgeon-Lieutenant-Colonel Baker (Bengal), Surgeon-Lieutenant-Colonel Fitzpatrick (Madras), and Surgeon-Lieutenant-Colonel Backhouse (Madras). The services of Surgeon-Captain Clarkson and Surgeon-Captain O'Kinealy are replaced at the disposal of the Government of Bengal. The services of Surgeon-Captain Street are placed temporarily at the disposal of the Government of Bombay. The services of Surgeon-Captain Vickers are placed at the disposal of the Government of Madras. The services of Surgeon-Captain Henvey are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces. Surgeon-Major Smith, Civil Surgeon, Shahjehanpur, has been appointed to hold Visiting Medical Charge of the Hardoi District in addition to his other duties. The names of the under-mentioned officers, whose promotion to the rank of Surgeon-Lieutenant-Colonel was notified in the *London Gazette* of June 17th, are as follows, and not as given in that *Gazette*: Sir George Scott Robertson, K.C.S.I., and Damodar Purshotam Warliker. A small committee, composed of two medical officers belonging to the Home and Indian Medical Services respectively, is about to meet at Simla to consider the question of modifying the field hospital equipment, with a view to its reduction, in the light of the experience gained during the recent operations on the frontier.

YEOMANRY CAVALRY.

Pembroke: James Wilson is appointed Surgeon-Lieutenant.

VOLUNTEER CORPS.

Light Horse: 1st Fifeshire: Surgeon-Captain A. Drysdale has resigned his commission but is permitted to retain his rank and to wear the uniform of the corps. *Artillery*: 1st Gloucestershire: Surgeon-Lieutenant W. Monckton has resigned his commission. *Rifle*: 1st Surrey (South London): Surgeon-Major C. S. Smith has resigned his commission but is permitted to retain his rank and to wear the uniform of the corps. 4th Volunteer Battalion the King's (Liverpool Regiment) Mr. J. H. P. Graham has been appointed Surgeon-Lieutenant. 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment: Surgeon-Captain W. H. Webb has been appointed Surgeon-Major. Surgeon-Lieutenant J. F. S. Clarke has resigned his commission. 5th Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Dr. James Pearson Brown has been appointed Surgeon-Lieutenant.

THE SPANISH-AMERICAN WAR.

Events have been rapidly moving of late in connexion with this war. The capitulation of Santiago and the Spanish evacuation of that city have taken place just at the right time for the United States, for an outbreak of yellow fever had occurred in the American lines, torrential rains were falling, and the situation of General Shafter's force, owing to the exposure of the troops and a breakdown in its supply departments, was becoming a serious cause of anxiety at Washington. Under such circumstances it was only to be expected that the hospital accommodation and medical arrangements were inadequate and left much to be desired. The storming and capture of the entrenchments of Santiago would, if stoutly defended, have been a formidable affair and have involved a serious loss of life. The Spanish troops, numbering some 10,000, are to be sent back to Spain, while a sufficient number of American troops will garrison Santiago to keep order, and the rest will no doubt be removed from the hot and unhealthy Cuban seaboard to the hills or return to America. It does not appear that there was any large amount of sickness or any actual famine among the Spanish troops at Santiago at the time of its surrender, but supplies were nevertheless running short, and a great deal of destitution prevails generally amongst the Cuban population. It has been decided to establish a large military hospital at Santiago, and to send a large additional force of medical men, nurses, and medical supplies there. The American troops who have taken part in the expedition to Santiago will not be fit for active service elsewhere for some time to come owing to the hardships which they have undergone and to the prevalence of disease — yellow fever and malarious types of fever and dysentery. According to late accounts there were between 200 and 300 cases of fever in hospital. The hospital ship *Solace* brought 48 wounded Spaniards to the States in a pitiable condition and they were transferred to a naval hospital for treatment. Peace is generally talked of, but there is no definite news as to the Spanish Government having made any official proposals or overtures to bring it about and the United States Government are losing no time in fitting out expeditions for the bombardment of Spanish ports and for the attack and capture of Porto Rico. Meanwhile they have bombarded Manzanillo and destroyed some Spanish ships. The Americans will yet have a difficult task in dealing with the Cuban insurgents who have assumed a hostile attitude towards them.

INVALID BRITISH SOLDIERS IN INDIA.

In THE LANCET of June 25th last we called attention to a question which had been raised in the House of Commons, after having been previously discussed in the columns of the *Morning Post*, regarding the establishment of hospitals and homes for sick and disabled soldiers. In connexion with that subject we pointed out that, as everybody knows who has had any personal experience of sickness, a man is not usually fit to return to his ordinary work on recovery or during convalescence from any illness if it has been at all severe in character. The recommendation that a soldier should be put on light duty or allowed to go on sick furlough does not sufficiently meet all cases; nevertheless, the present method of providing light duty for soldiers discharged from hospital might no doubt be largely extended with advantage to them and to the service. We learn that under instructions from the Secretary of State for War a General Order has been published in India notifying that in order to check if possible the waste which is caused by the invaliding of young British soldiers it is desirable that a certain time may be allowed to pass after the discharge of men from hospital before they are called upon to perform their full duties as soldiers. With a view to attaining this object officers in medical charge of British troops on notifying to commanding officers that soldiers have been discharged from hospital will, when they consider it advisable, state from what particular duties and for what period such men should be exempted.

REVISED FIELD MEDICAL EQUIPMENT.

We have received a description in pamphlet form of the Revised Field Medical Equipment (1898 Pattern) promulgated by Army Orders dated July 1st. The "field medical companion" will in future be known as the "medical companion," the special surgical panniers as "field surgical panniers," and the box of apparatus for fractures and dislocations as the "general fracture box." An antiseptic case (weight about 43 lb.) has been added. Compressed drugs, termed "tablets," have been extensively adopted. The amount of anæsthetics carried has been

Digitized by Google

largely increased. All surgical instruments are metal handled. Sterilisers (field pattern) have been added. In the panniers and fracture box, splints have been entirely abolished and perforated zinc substituted, together with tools for making it into splints. All field medical units are now supplied with operating tables.

SURGEON-GENERAL W. TAYLOR.

Surgeon-General Taylor had the honour of forming one of a party of officers dining with the Queen and Royal family previously to embarkation for Egypt to take part in the forthcoming expedition to Khartoum. Surgeon-General Taylor, as we have already intimated, will act as principal medical officer of that expedition and subsequently, on completion of that service, will proceed to India as Surgeon-General and principal medical officer of Her Majesty's forces in relief of Surgeon-General Gore, who will go on the retired list in December next.

ENTERIC FEVER AT OOTACAMUND.

There has been a good deal of enteric fever prevailing of late at this favourite hill station and the Madras Government have appointed a committee to inquire into and report upon the causes of it.

We are glad to hear that Surgeon-Major-General Cleghorn, C.S.I., of the Indian Medical Service, has recovered from the results of his late accident while bicycling.

Correspondence.

"Audi alteram partem."

A PROPOSED SCHOOL FOR TROPICAL DISEASES.

To the Editors of THE LANCET.

SIRS,—Sir H. Burdett in the *Times* of July 11th writing of a proposed school for tropical medicine, states that "the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich, as well as of the branch hospital, together with a number of teachers specially selected and attached to the new school." This was the first intimation of any kind that we had that such a scheme was on foot, and the statement was made without our authority or consent.

We are, Sirs, yours faithfully,

JOHN CURNOW, M.D., F.R.C.P.Lond.,
JOHN ANDERSON, M.D. St. And., F.R.C.P. Lond., } Visiting Physicians.
G. R. TURNER, F.R.C.S.Eng., Visiting Surgeon.

Dreadnought Seamen's Hospital, Greenwich, July 18th.

"REGINA *v.* COLLINS": A PLEA FOR AMENDED LEGISLATION.

To the Editors of THE LANCET.

SIRS,—It would serve no good purpose to dwell in the page of a professional journal on the unspeakably low moral tone of so-called "society," on which the revelations of the recent trial have thrown such a lurid light. The sentiments of the community have already found adequate expression in the columns of the lay press—notably the *Times*—whose fearlessly outspoken article has rendered a distinct service to the cause of public morality. Rather, with your kind permission, would I remind my professional brethren that this trial has once more called attention to the exceedingly shadowy nature of our privileges as duly registered members of the medical profession. When the general public learn, as in this case, that an unregistered man may engage with perfect impunity in medical practice until his career is checked by conviction for felony they not unnaturally ask what the privileges of registration really mean. Briefly they are somewhat as follows. We may sign valid certificates, we may offer ourselves as candidates for public appointments, and we may claim (though we may not always obtain) our fees in a court of law. Apart from this our position is aptly described in the following extract from the leading article in the *Times*: "He [Collins] must have known in what degree his calling was esteemed, or he himself as a member of it, when he found that his patients were as ready to honour him with their confidence after he had been convicted of felony as before, and that a trifle of this kind scarcely at all affected his position." Significant words, and only too true.

A duly enrolled solicitor is adequately protected by law against unscrupulous competition on the part of those whose names have never appeared in the Law List or whose misconduct has entailed their removal from it. The same protection is afforded to duly ordained clergymen of the Church of England. Why, then, should duly registered members of a profession not a whit less honourable be obliged to share the right of practice with anyone possessed of sufficient self-assurance to make a show of professional skill and sufficient cunning to keep within the generously defined bounds imposed by the existing law? Your columns have again and again exposed this absurd and indefensible anomaly. May we not hope that the General Medical Council, as custodian of our Register and of the honour of our profession, may find an early opportunity for urging on our legislators the necessity for some amendment of the present statutes? I feel confident, Sirs, that your powerful aid will not be wanting and that you will allow the subject to be thoroughly ventilated in your columns.

I am, Sirs, yours faithfully,

T. R. HENDERSON, M.B. Edin.

Bedford-hill, S.W., July 5th, 1898.

"A PHYSICAL BASIS IN THE DRUNKENNESS OF WOMEN."

To the Editors of THE LANCET.

SIRS,—I am much obliged for your paragraph on this matter, for its criticism is at least much more kindly and fair than most of that which I have come across.

In most instances I am wholly misrepresented because of a ridiculously garbled and inaccurate report prepared for one of the reporting companies which appeared in most of the morning papers. Even your paragraph falls into one error in which you make me say that I recommend the use of alcohol in treating the inebriety of women. This is not the fact. What I did say was that in the climacteric drunkenness of women I did not regard total deprivation as necessarily a part or always a safe plan. That men and women in the better ranks of life differ materially in their ways of abusing alcohol is a fact which no one can dispute. That there is a specific drunkenness amongst women confined to the climacteric period is a point on which I want the eyes of my profession to be opened. I have often declared it, but my work has so far received no recognition. But I know it not only as a practitioner but as an intimate friend and relation of some of its victims.

That the agonising suffering induced by chronic pyosalpinx and kindred ailments will induce the victims to the periodic abuse of alcohol and morphia, and that these habits may be cured as the sufferings are by surgical treatment, are facts which are proved up to the hilt by my surgical records. My brethren may dispute my conclusions as much as they like, but if they bear my statements in mind and look about for evidence they will not be long before they find that the facts and my statements run together.

Having arrived at such conclusions it seems to me a terrible thing that women may, under the Government Inebriates Bill, be put in prison because they are the victims of curable surgical ailments.

I am, Sirs, yours faithfully,

LAWSON TAIT.

Newhall-street, Birmingham, July 18th, 1898.

"ARSENIC IN WOOL."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a letter in THE LANCET of July 9th under the above heading. My only reason for referring to this correspondence is to correct a misapprehension on the part of the writer of the letter, who says: "I believe it is nearly if not quite impossible to buy any sheep's wool (home or foreign grown) which does not contain arsenic." This is a mistake, for while it is quite true that the great majority of sheep are arsenic-dipped a very large number are dipped with other substances, principally carbolic dip, next tobacco, and a considerable number with lime and sulphur. I manufacture, for home and export trade, both arsenical and carbolic sheep dips, and I find that exactly 20 per cent. of my total output last year was carbolic sheep dip; fully 80 per cent. of this carbolic dip was

Digitized by Google

exported to the colonies and to South America. There are at least ten or a dozen other firms making both varieties of sheep dip for home and foreign trade, some of whom I am sure sell a larger proportion of carbolic dip.

I am, Sirs, yours faithfully,

Oban, July 18th, 1898. ALEX. ROBERTSON.

TRANSPERITONEAL LIGATURE OF THE ILIAC ARTERIES.

To the Editors of THE LANCET.

SIRS,—A paper on this subject which may have escaped Mr. Frederick Page's notice was published by Dr. Thomas S. K. Morton, Professor of Surgery in the Philadelphia Polyclinic, on Jan. 15th, 1898, in the *Journal* of the American Medical Association. Dr. Morton collected 29 cases, including one operated on by me.

I am, Sirs, yours faithfully,

Liverpool, July 18th, 1898. F. T. PAUL.

SWALLOWED COINS.

To the Editors of THE LANCET.

SIRS,—In reference to Mr. Robson's cases of removal of impacted halfpennies from the œsophagus I may mention that I have quite lately had under my care a boy, aged ten years, who swallowed a penny. The x rays revealed the foreign body in the stomach some 10 days after the event. He was kept on dry food and in about 20 days the boy passed the coin *per anum*. The parents were foolish and purgatives were as usual administered. It is interesting to know that so large a coin as a penny can be swallowed by a small boy and safely pass the pyloric and ileo-cæcal valves, and points to the lesson that we should not be in too great a hurry to operate in such cases.

I am, Sirs, yours faithfully,

July 20th, 1898. A. MARMADUKE SHEILD.

"THE DRAINAGE OF SWANAGE."

To the Editors of THE LANCET.

SIRS,—As medical officer of health of Swanage I must protest against your annotation headed "The Drainage of Swanage," which is calculated to give a wrong impression and lead visitors to suppose that our town is in a very insanitary condition. It is true that we are waiting for the late autumn to carry our drainage outfall further out to sea, but practically the present outfall is no nuisance to the bay or town owing to the comparatively small amount of sewage passing through it; and the distant outfall is to be constructed under the impression that Swanage will rapidly increase in size. What is of more importance is a pure supply of water. This, we are thankful to say, we have, and since I have been medical officer of health, a period of over eight years, there has not been a case of typhoid fever in the town and diphtheria is practically unknown. Unfortunately our council has not adopted the Notification of Infectious Diseases Act, but my brother practitioners are always willing to let me know if they have any infectious cases under their care and I may safely say that we are now free, and have been for months past, from any infectious complaints. I am, Sirs, yours faithfully,

A. S. MCCAUSLAND, M.D. Brux., L.R.C.P. Lond., M.O.H.

Swanage, July 19th, 1898.

P.S.—The *Bournemouth Guardian* you quote from is the organ of a rival watering-place whose medical men and residents frequently come to Swanage for the benefit of the bracing air during the summer months.

*** Our contention is that the sanitary defects pointed out by Dr. S. W. Wheaton in his report made in 1897 still remain. We are glad to hear there is neither typhoid fever nor diphtheria, but are not the conditions in Swanage such as to favour the spread of these diseases should they arise?—ED. L.

CHURCH SANITARY ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—Will you kindly permit me to make known to your readers the aim of the Church Sanitary Association? The object of the society is to aid, by means of the Church's institutions in every parish, in securing for all fresh air, pure water, abundant light, proper food, improved dwellings, wholesome surroundings, and the greatest possible immunity from infectious diseases. With county councils, district councils, and parish councils ready to put into effect the judgment of sanitary officers it is all the more necessary for the preacher to drive home the lesson that man is his "brother's keeper." I am, Sirs, yours faithfully,

F. LAWRENCE, Hon. Secretary.

Church House, Westminster, S.W., July 15th, 1898.

*** We print this letter with pleasure, but our previous allusions to the society must have made its scope familiar to our readers.—ED. L.

BONE-SETTERS AND THE EMPLOYERS' LIABILITY ACT.

To the Editors of THE LANCET.

SIRS,—I wish to ask your opinion on a class of individuals who call themselves "bone-setters." A duly qualified and registered man is called in the first instance to an accident and pronounces it a fracture of both bones just above the ankle. Afterwards a "bone-setter" is employed without in any way informing the medical attendant and tells the patient's employers that "his spiel bone is broken and his ankle put out." I had to see the patient as surgeon for the employers under the new Act and in my opinion the surgeon who first saw the case is right. It was fifteen days after the accident before I could examine and thanks, no doubt, to the interference of the quack in the interval the swelling was still so great that the parts could scarcely be made out. What I want to know is, firstly, whether any objection can be raised by employers as to the compensation to be granted when joints and limbs are mauled by an unskilled and unqualified person who takes upon himself the duties of a surgeon; and secondly, whether the General Medical Council can and will protect us, as otherwise of what avail are our long and severe curriculum, our searching examinations, and our strict registration laws? We have to contend with men who have neither science nor a spark of gentlemanly instinct on very unequal grounds. I, and no doubt many others, could give you some terrible results from the interference of these impostors.

I am, Sirs, yours faithfully,

JOHN CRANKE, L.R.C.P. & S. Edin., &c.

Ulverston, July 19th, 1898.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING IN EDINBURGH IN 1898.—CONSTITUTION AND CONDUCT OF THE ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—I shall be glad if you will allow me to intimate to those of your readers who are interested in the proposed alteration in the by-laws that an informal meeting will be held on Monday evening, July 25th, in the chief class-room of the new School of Medicine of the Royal Colleges, Bristo-street. The chair will be taken at 9.30 o'clock precisely, and the proposals bearing upon this and other questions will be considered with a view to facilitating discussion thereon when brought before the general meeting. I trust that as many of those members who have reached Edinburgh and are able to will make it convenient to attend. The best train from Manchester will leave Victoria on Monday at 12.50, reaching Prince's-street at 6.5, and I shall be glad if anyone wishing to go by that train will let me know by Saturday night's post so that carriages may be reserved.

I am, Sirs, yours faithfully,

Old Trafford, July 18th, 1898. JAMES BRASSEY BRIERLEY.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—Your correspondents on this subject seem to be extreme, and if you will permit me to give my impressions from a long and varied experience of both sides of the question it may perhaps be of interest. I must say that the

Digitized by Google

six years I acted as assistant in three or four different parts of this country, different classes of practice and both in-door and out-door, I lived as I never lived before or since and enjoyed the best of health. I had plenty of sport and amusements and time therefor and never had to complain of any want of consideration on the part of my principals, and in those days of a plentiful supply of assistants I had no difficulty in getting a post at £150 out- or an equivalent in-door and was always offered an increase if I chose to remain on. Then when I purchased a share in a practice my troubles began and were little diminished when in a few years I succeeded to the whole. It was, as your correspondent describes, slavery day and night, no time for recreation and expenses about half the receipts; consequently, according to the old proverb continual dropping "wears away (even) stones," my health broke down, I had to sell out and take a year's rest to undo the results of trying to earn my living in a country practice. My experience of even a good-class country practice is that I would far prefer an appointment of £200 a year clear and work proportionately. As to assistants, I believe that a steady, reliable man can command a good salary and every consideration from his principal. I have only had experience of two. One was a drunkard and the other was most unsatisfactory. A medical man who considers his own interest will do anything in reason to make his assistant comfortable and settled, otherwise he will injure his practice, give himself any amount of trouble and worry, and yet not harm his assistant. In fact, an assistant can easily lighten his work by frequently changing or by making himself unpopular should his principal not choose to make him comfortable or to remunerate him properly. I cannot understand the position of your correspondent "Practitioner"; he was first an assistant, then had a practice, then a partner at No. 1, and now has a practice of his own at £400 a year. I think the fact of a man working practically "night and day" for £400, keeping two horses and possibly a bicycle, and a £40 drug bill, and requiring an assistant "badly," shows that in selecting a practice he has come upon a *rara avis*. I have practised in one of the poorest and most scattered of agricultural districts where the union appointment was worked at a loss, almost all the remaining population in clubs, and midwifery all round averaged 15*s*. a case, and yet I almost doubled the income of your correspondent. There is no doubt but that if medical men were more in union their conditions of life and remuneration would be far better.

Some years ago I received an offer of over £200 a year and light work from an unqualified man doing at the rate of £900 a year, which I, of course, unhesitatingly declined; this man had got well-qualified men to do it before and no doubt got them to continue to cover him in his work. Again, when I purchased a practice the remuneration as district medical officer was so reduced that I would have declined it until raised to a fair sum, but I had to contest the appointment with an opponent and gladly accept it to be worked at a pecuniary loss. Medical men, I believe, are in a great measure to blame for their own grievances. Nevertheless, I agree with your correspondent that it is not a profession a great many of us would again select had we the chances and opportunities of our youth.

I am, Sirs, yours faithfully,

July 11th, 1898. LOCUM.

To the Editors of THE LANCET.

SIRS,—The letter of "Practitioner" in THE LANCET of July 9th seems to me to have struck the keynote of the above question, but at the same time he does not go far enough in that he gives no explanation as to why the principals are not in a position to pay a good salary. This I believe I have found a solution for, and it is summed up in the expression "medical fees." These not being laid down by law, as are legal fees, have simply been cut down to below a living wage because men desire to have large practices, and that they do have an immense amount of work for a small return is well known, since the public is notoriously fond of the cheapest article though it is not always the best. From past experience I know that a principal who charges a respectable fee of 3*s*. 6*d*. or 5*s*. a visit and who will not see a patient at home for less than 2*s*. is well able when he requires an assistant to pay one well, but those men who have dragged down the profession by accepting fees of 1*s*. for a visit and medicine or 5*s*. for a week's attendance, including medicine and sometimes a night visit, plainly, even though they have a very large *clientèle*, cannot afford to pay a good salary for a qualified man, but when in need of an assistant are forced to make an offer, similar to one in a medical journal of a few weeks back, of £10 per annum in-door, for we all know how many cases at 1*s*. a visit will have to be treated for a return of £300 a year. My contention is, that the medical profession should unite to get a legally recognised fee and those who cannot afford to pay it should be treated either by the hospitals or the parish medical officers, instead of individual practitioners vying with each other in cutting down fees, thereby creating a state of constant work for a starvation wage. In conclusion, may I ask the medical profession to endeavour to elevate it by preserving a respectable fee in the knowledge that "the labourer is worthy of his hire."

I am, Sirs, yours faithfully,

July 16th, 1898. M.B., B.CH. DUBL.

SANITATION AT GIBRALTAR.

(FROM A SPECIAL CORRESPONDENT.)

IT does not come within our province to insist upon the importance of Gibraltar as a fortress and military station. The strategical advantages of holding this Crown colony are fully appreciated, but it is necessary to insist that the military value of the station is dependent to a great extent on its sanitary condition. Fortunately this is a point of view which has not been neglected and very great improvements have been effected. In spite of the increase of population there has been a steady decrease in the death-rate. Thus the mean annual death-rate for the sixteen years from 1851 to 1866 amounted to 29·25 per 1000. The improvement then commenced, and during the ensuing four years the mean death-rate was only 24·61 per 1000. For the next fifteen years the quinquennial average did not reach 24 per 1000 and did not fall below 23·68 per 1000. From 1886 to 1890 the average was 22·44 per 1000. This brings us down to the present epoch, and it will be found that there has been a still greater improvement. Indeed, Gibraltar may now aspire to be compared with the larger towns of England and Wales. Thus in the year 1891 the death-rate did not exceed 18·95 per 1000 and for the five years 1891–95 the average was 19·97. In 1896 the death-rate is set down at 19·52 per 1000; but 1897 was a very bad year, for the death-rate then rose again to 23·56 per 1000. The main sanitary defect at Gibraltar is overcrowding, and it is in regard especially to infant mortality that the colony compares unfavourably with English towns. The birth-rate in 1897 was equal to 31·34 per 1000 and the deaths of infants under one year old was equal to 184·9 out of 1000 born. The principal causes were zymotic and respiratory diseases. The average zymotic death-rate for the entire population was 2·89 per 1000 from 1891 to 1895. It amounted to 2·25 per 1000 in 1895, to 2·69 in 1896, and to 3·77 in 1897. Measles and diarrhœa were the most fatal zymotic diseases in 1897. Pulmonary tuberculosis and respiratory diseases such as bronchitis, pneumonia, &c., caused a death-rate of 7·01 per 1000 in 1897 and 5·23 per 1000 in 1896. Thus, though there has been a general improvement up to 1896, the serious relapse which occurred last year suggests that the general condition of affairs at Gibraltar is not yet absolutely satisfactory. The fact is that the problem of overcrowding has not been solved, nor is it likely to be solved unless the military authorities resign themselves to the necessity of largely increasing the area on which the building of dwellings is sanctioned.

Unfortunately there are at Gibraltar two sets of interests which are diametrically opposed. First, there is the military interest, which would make Gibraltar simply a fortress with scarcely any civil population. Secondly, there is the trading interest, which finds that Gibraltar is a most convenient commercial centre and would soon convert the place into a vast emporium for trade with Spain and the Mediterranean. As usual in such cases neither party has its own way. The trading element is cramped, impeded, and checked by the military element; but, on the other hand, the military authorities have not succeeded in preventing Gibraltar from becoming a very important commercial centre. They have mainly succeeded in producing the excessive overcrowding which is the principal cause of the high death-rate. British

Digitized by Google

capital and British enterprise have acted like a loadstone in attracting the poorer populations of the neighbouring countries. The right of residence is refused absolutely to foreigners, but it cannot be refused to British subjects, and these include a number of natives from Malta who overcrowd the poorest tenement houses.

The Maltese workmen and labourers are content to live huddled up together in badly ventilated, damp rooms, tainted with decomposing organic matter. Their linen is washed and dried in small inner courts or patios where the sunshine cannot penetrate and where foul water stagnates on the ground. Under these patios tanks receive the rain-water which, though contaminated by the emanations from the yard, is sometimes used for drinking purposes. It is very difficult to inculcate principles of hygiene among the poorer sections of the population. They cannot be persuaded to open the windows to ventilate the rooms where the sick are being nursed. On the other hand, they still believe that by applying the entrails of pigeons, lamb's fat, and other so-called remedies to parts of the patient's body they will cure the disease. To counteract such ignorance and the over-crowding the very best domestic drainage and sanitation generally are most necessary. Much has been done in this respect, but new defects are being constantly discovered. Thus in 1892 some 127 underground tanks were dealt with by the sanitary authorities but a great number of old surface wells situated close to sewers and house drains were not touched, though half of them contained water proved by analysis to be suspicious if not absolutely dangerous. Fortunately the well water has a tendency to become brackish and therefore cannot often be used for drinking purposes. On the other hand, the rain-water may be contaminated on the roofs of the houses where it is gathered. Thus, in his report for the year 1892, Surgeon-Captain Macpherson, who was at that time medical officer of health, states that in one case the soiled mattress, towels, and clothing from a tenement where there was a case of enteric fever were found lying upon the terrace. On two other terraces refuse-buckets and slop-pails were kept and on one terrace, also connected with the water tank, a pigeon roost was installed. The water here collected was proved on analysis to be excessively impure. In another house there was a well-manured garden on the terrace. The water collected was found to be full of micro-organisms, and there was a case of typhoid fever among the inhabitants who drank the water in question.

It will be seen, therefore, that the question of water-supply is one of the most urgent sanitary problems with which the authorities have to deal. There are in the civilian portion of the town 690 underground private water-tanks which receive rain-water from the roofs and terraces and can store 7,535,504 gallons. In many houses these tanks are not large enough, and there are 170 houses which have no tanks. During the year 1897 no less than 273 of these private tanks were inspected, repaired, and cleaned. Apart from this private supply there is a public supply collected by the Sanitary Commissioners from the upper slopes of the Rock and conveyed by gravitation to a reservoir near the Moorish Castle which has a storage capacity of 1,257,444 gallons. This water is sold to the inhabitants at the rate of ten gallons for one penny. During dry seasons when the supply fails sea-water is distilled and sold at the rate of five gallons for one penny. This, as will be seen, is not a very satisfactory arrangement, and under the direction of Mr. W. Wallace Copeland, C.E., a comprehensive scheme for an increased water-supply is now being carried out. Tunnels are being dug into the rock, and inside the mountain, well away from all danger of bombardment, four great reservoirs will be constructed with a capacity of 5,000,000 gallons. The catchment areas, 21½ acres in extent, are to be covered over with concrete; and when this is done there will be enough water for the population and the shipping; though as matters now stand it is necessary to distil more than 3,000,000 gallons of sea-water in the course of the year. The rain-water will be passed through polarite filters and will be stored in absolute darkness. Doubtless when this work is completed an improvement in the health of the population will result.

The difficulty due to overcrowding will, however, still remain. In his report for 1894 Surgeon-Captain Macpherson says: "One-room tenements are necessities here in consequence of the lack of house accommodation and the high rents demanded, and very nearly half the families in Gibraltar occupy such dwellings." Out of 83 cases of small-pox which occurred in Gibraltar during that year 41 patients occupied one-room tenements and 12 two-room tenements. From one point of view, however, the evil resulting was greater in the better-class houses, because the patients were not removed to the isolation hospital and consequently others contracted the disease from the first case. According to the by-laws removal to the hospital can be enforced when the rent paid does not exceed 50 pesetas per month. Thus though first cases occurred more frequently in the poorest houses they were more easily dealt with and further mischief was prevented. Though overcrowding has not been materially checked a great deal has been done in regard to the compulsory notification of infectious diseases, including measles. This disease appears periodically in epidemic form. Thus in 1887 there were 861 cases of measles and there had been 2157 births since the previous epidemic. This gives a proportion of 39 cases per 100 births. In 1890–91 there were 560 cases out of 1568 births, or a proportion of 35 per cent. But in 1894, when much more energetic measures were taken, there were only 173 cases out of 1304 births, or a proportion of 13 per cent. On the latter occasion each case was visited and all the members of the family were kept away from school. Sanitary inspectors made daily visits to the houses where cases had occurred and insisted on the isolation of the patient and on ample ventilation. Only 5 deaths ensued But in 1897 a more severe epidemic visited the town, for there were 13 deaths and 252 cases. At the same time there were 65 cases of diphtheria, of which 18 proved fatal. A large number of these cases followed a very mild course when antitoxin was administered at an early stage. In spite of these unfavourable figures it would seem as if the prevalence of diphtheria was decreasing. Thus, during the quinquennial period from 1886–90, the average death-rate from diphtheria amounted to 1·20 per 1000, whereas during the period 1891–95 it was only equal to 0·36 per 1000. The gratuitous distribution of antitoxin, the more strict supervision over the milk-supply, and general sanitary measures have helped to bring about these results. On the other hand, the disinfecting service is not yet satisfactorily organised. The bedding, linen, &c., from private houses are taken to the Colonial Hospital, where there is a disinfecting stove; but to light this stove involves a certain amount of trouble and expense. There is a segregation block in this hospital where cases of scarlet fever, diphtheria, or measles are treated, and when the hospital authorities have to disinfect for these patients then they do not object to disinfect at the same time the objects sent in from outside. As a result of this state of affairs people are kept waiting a considerable time before they get their clothes back. It is evident that the sanitary authorities should have a disinfecting stove of their own and not be dependent on the goodwill and leisure of the hospital authorities.

Another serious matter is the want of accommodation for laundry work. A great part of the dirty linen from Gibraltar is taken over the lines to Spain, where it is washed in what often prove to be very unwholesome surroundings. On the other hand, many dwellings in Gibraltar are not provided with proper washhouses nor are there convenient means of drying the linen. A large sanitary laundry with modern appliances is much needed. There are no public wash-houses.

Of course, Gibraltar, like most other towns, is much perplexed and troubled by the general question of drainage. A new main sewer has been constructed and it has a length of 13,300 ft. and a flushing tank which holds 1600 gallons of water is connected with this main. This is brackish water pumped up from the north front, used exclusively for flushing purposes and watering the streets. It is known as the sanitary water and is much too salt to be mistaken for drinking-water. It is thought that the flow in the sewers will now be improved and greater internal cleanliness maintained. For the small district called Irishtown, which is situated between this main sewer and the shore and therefore at a lower level, Shone ejectors will be employed to raise the sewage and to throw it into the main. Nevertheless this does not solve the problem of sewer ventilation, which greatly troubles the inhabitants of Gibraltar. Perhaps the sewer air will be less objectionable, but it is too much to hope that it may cease altogether to create a nuisance. From time to time there have been complaints of the odours issuing from manholes, and then these have been closed, so that a greater amount of sewer-air has gained admission into the surrounding houses. Much of the trouble has arisen from the fact

Digitized by Google

that the radical difference which exists between the laws governing the currents of air in Gibraltar and in England had not been realised. In England the sewer air is warmer than that of the street above, at least during about ten months in the year; in Gibraltar the contrary is the case. The sewers are cold in Gibraltar, whereas they are warm in England and it is the difference of temperature which governs the currents. The principal cause of ventilation, the ascending property of the heated air, which secures the ventilation of the sewers in England, does not exist in Gibraltar. The flow and the rise and fall of the sewage are also active ventilating forces. In England the water is generally at its highest at midday and at its lowest at 3 A.M. This acts like a sort of bellows blowing the air out and then drawing it into the sewers. But at Gibraltar there is so little water that the rise and fall of the sewage is almost imperceptible unless there is a storm; then the effect is most distressing. The sewer air, long pent up, is suddenly forced out and the stench is such that it will awaken the soundest sleeper. The inflow of a sea wave caused by the wind blowing in the direction of the sewer mouth or the passage of a strong wind over the top of a sewer ventilator may produce the same effect. The long-stored sewer air thus extracted, being heavier than the outside atmosphere, descends on the neighbourhood and is not promptly dispelled. Under these circumstances, as the sewers at Gibraltar cannot ventilate themselves they must be ventilated by artificial means. The erection of a destructor would render great service and the furnace might be utilised to draw up and burn the sewer air. Some ventilating fans might also be employed, as in coal mines, to move the air in the parts of the sewer which are too far away to be affected by the fire of the destructor.

Thus Gibraltar needs more house-room so as to prevent overcrowding, a much larger water-supply so that the inhabitants need not drink the rain-water gathered on the roofs and terraces of their houses where it can be easily contaminated and which is also stored in tanks under the houses where again it may be befouled by dirty water from the drains, the surface of the yards, or the streets. Then there must be an efficient means of sewer ventilation, and probably mechanical means will alone ensure a satisfactory and uniform result. Again, there is urgent need of accommodation for the proper washing and drying of linen at Gibraltar, and the sanitary authorities should have a disinfecting stove which could be used at all hours and immediately it is required. There should also be a reception house where families might live for a day or two while their homes are being disinfected. Though the food-supply is on the whole of good quality and the markets are clean and well supervised the itinerant milk-vendors who come over from Spain should be compelled to take out licences and should be placed under efficient control so as to prevent adulteration.

All these observations, it will be seen, mainly concern the health and interests of the civil population, but the garrison has also its share of grievances, though it is not so easy to ascertain the details. The authorities are reticent because they have been recently subjected to some very severe criticisms. The sense of discipline is such that no one dares to speak for fear of incurring the displeasure of a superior authority. However, I was very courteously allowed to visit the Military Hospital, one of the institutions which had been abused in very strong language, and certainly it is not easy to speak favourably of this building. Indeed, what can be said of a hospital which dates back to the year 1792? Is it likely that at that date modern principles of hygiene would be applied? On the other hand, it must be recognised that the plan of the building is eminently suited to the climate. There is a large inner yard surrounded not merely on the ground floor, but also on the upper floor, with a very broad verandah. The yard is so large that numerous orange trees grow in the centre, and being square in shape there are always two sides where shade can be enjoyed. Thus the patients without having to go up or down stairs can sit or lie out in the open and in the shade. The wards have had ventilators added, so that a current of air can be established even when the windows are shut. Then there are windows on both sides of the wards, so that there is no lack of air and light; but nevertheless the building is altogether unsuited for a hospital. The ceilings are held up by any number of large wooden rafters which form countless angles and inaccessible dark corners where microbes and dust can accumulate without let or hindrance. Nor is the hospital provided with an operating room. There is, of course, a room in which operations are performed, but it can in no wise be qualified as an operating room, for it does not differ from any other room and possesses all the sanitary defects inherent to the entire building. It does not even contain the special furniture associated with an operating-room. Certainly, there is an old wooden operating-table, but this quaint bit of furniture would best serve for a museum or an historical exhibition of the surgical appliances of a bygone age.

These grave defects are, however, in a great measure compensated for by British cleanliness, the Gibraltar climate, and the topographical situation of the hospital. These are the real life-giving forces which prevent the disastrous consequences which would probably result if such a hospital existed in, for instance, the neighbourhood of London. The hospital stands on a ledge of the rock, overlooking the sea on the Atlantic side, well away from the town and at a sufficient elevation from the sea to enjoy a greater movement of air than exists on the lower levels. The climate allows door and windows to remain wide open the greater part of the year. It rains so seldom that there is rarely any difficulty in placing a patient in the open air. The open-air treatment and sun baths can be enjoyed nearly all the year round, and this will go a long way to compensate for the effect of dust-harbouring rafters. Of course, it is difficult to prevent the defects inherent in a building which is more than a century old, but there is an air of parsimony about the place which certainly need not exist. Undoubtedly economy is a virtue but it can be pushed too far. It seems as if the fear of spending money has undue weight. Thus it is difficult to get over from England new and more expensive medicaments. The supply of bandages, I ascertained, is so limited that even in these times of peace absorbent wool and such articles have been known to run short before the end of the month. If in this respect I am correctly informed it would be impossible to protest too strongly against such niggardliness. Not only should there be bandages, &c., in store to satisfy all likely demands arising in times of peace, but there should be enough to meet to the full the exigencies of war. It is not after war has been declared that we would have time to think about sending absorbent wool to Gibraltar. These are precisely the sort of details which should be thought out and completely organised in advance. If there has been neglect in this matter or unwise economy then a very heavy responsibility rests on the authorities concerned. Officials may seek to make themselves popular with their superiors or with the Government by reducing the expenses of their department, but this must not be done at the sacrifice of efficiency. In bringing this grave question forward I can only hope I have been misinformed, but I hold my information from such good sources that I feel at least justified in demanding that an inquiry should be made to see if the economy practised has not been carried to the point of sacrificing efficiency.

THE SPANISH-AMERICAN WAR.

(FROM A SPECIAL CORRESPONDENT.)

On board U.S. Hospital-ship *Relief*, July 3rd, 1898.

THIS beautiful ship got safely off on the first log of her journey late yesterday and if a peaceful sea and sunny skies are omens for good surely she will bring comfort and relief to our brave men in the field. Our progress down the bay of New York was marked with the wildly enthusiastic tooting of many whistles. It seemed more like a triumphant return from duty well done and must have touched the heart of our commanding surgeon. People crowded the rails of the ferry-boats and cheered long and heartily. The *St. Paul*, looking as if she were in bad humour and longing for another torpedo-boat to eat up, dropped her flag in a dignified way as we passed; the huge *Campania* gracefully did the same with the Union Jack, and with a funny little squeal from a tiny launch we slid out to deeper waters.

It is really difficult to do justice to the absolute completeness of this floating hospital; already things have been put into shape and surgeons, nurses, and hospital stewards seem to have caught the spirit of the surgeon-in-chief and those at home need have no fear but that

Digitized by Google

this ship is destined to accomplish great things. There are two chaplains on board, the Rev. Mr. Robinson and Father Connelly. Each held a simple service on deck this morning and asked a blessing on this mission of peace. Both are unaffected Christians whose ministrations will bring consolation to many a poor fellow who is suffering or dying in this war. We stop at Fortress Monroe for a few hours this afternoon and then go to Santiago, where we are due some time on July 7th.

With reference to certain statements recently made in a temperance journal called the *Voice*, recalling certain unfortunate incidents in the Civil War, I have questioned a number of army officers as to the use and abuse of alcohol in that service and they, without exception, affirm the "good habits" of officers and men. The Rev. Mr. Robinson, the chaplain of this ship, tells me that in twenty-two years of service he can recall but one case of an officer being intoxicated on duty, and says it is a pleasure to be able to attest the self-restraint exhibited by our officers in all such matters both on and off duty. He agrees with me in believing that no good purpose can be served by raking up old scores now, over a third of a century after their occurrence. In the old days there was much drinking in both the army and the navy, but that time happily is past, and all who know anything about these branches of our Government recognise this fact and are happy and proud to give credit where credit is due.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague in Bombay, Karachi, and Calcutta.—The System of Appointments in the Government Services.

THE increase in the number of deaths from plague during the past week in Bombay should not be without its warning. A jump from 15 to 53 cannot be accidental, and distributed as the cases have been in different parts of the city it behoves the authorities to make every preparation for a recrudescence. A certain district called Mandvi, where the disease is supposed originally to have broken out, still remains the one spot which is continually recording its cases. In fact, from this particular area it has never been absent. In other respects the health of the city is remarkably good, and what is particularly noticeable is the exceptionally low mortality from fevers. One would almost imagine that the two epidemics had in some way cleared the air. What is perhaps still more remarkable is the almost entire absence of cholera. Karachi is not yet quite free, but the cases are reduced to two or three a day. An experiment to be watched here will be to see whether a redevelopment of the disease occurs when the 30,000 people now out in camps are allowed to return to their homes. The first case of plague among Europeans in Calcutta has just been recorded. The number of cases reported daily is small but steadily continues, and there must be the ever-present danger of a development at any moment. A total of 156 cases has been recorded, with a mortality of 71 per cent. About 2000 persons have so far been inoculated—an utterly insignificant number to have any effect on the possible development of the epidemic.

The system of appointments in the Indian Medical and Civil Services is open to much abuse. One constantly hears that So-and-so has been very fortunate in obtaining some particular berth. It is well known, however, that the so-called "luck" depends upon patronage. With the Civil Service the medical profession has of course little concern, but in both services the evil must be equally detrimental. If it does nothing else it stifles independence of character and original work. It would perhaps be equally unsatisfactory to grade the various appointments and to fill them by a process of pure seniority. The essence of the evil as it exists now probably lies in the power of patronage given to certain officials. A possible solution of the difficulty in properly filling up these posts might be found by the appointment of an independent board. Such a board with definite instructions to appoint on certain definite lines might certainly remove some of the anomalies and grievances which now exist. The Government services naturally attract a large proportion of the ablest men and the appointments under Government should be far removed from the semblance of favouritism. The best work will never be obtained until this principle is recognised and acted upon.

July 2nd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Hospital Question.

THERE are indications that before long the "infirmary question" will again lend itself to controversy. The last pronouncement of the infirmary board was to the effect that they could not entertain the proposition for the sale of the whole of the site. When the vote of the infirmary trustees was taken about a year and a half ago there was a majority of 46 in favour of rebuilding on the present site, but only 853 votes—about two-thirds of the full number—were recorded. A meeting of the trustees is to be held shortly and the question is to be put to them again. The present site cannot serve for rebuilding on the enlarged scale which will be necessary, and if the infirmary is to remain in the centre of the town more adjoining land must be purchased. This will necessarily be costly and will require some closing and rearranging of streets. The infirmary site is the finest—indeed, almost the only fine one—in the city, and longing eyes are sometimes cast on it as being so admirably adapted for a fine public building. Manchester is said not to have one on a site worthy of itself, and that may indeed be said of the town-hall, the assize courts, and Owens College. They all want lifting up. Manchester needs an art gallery and a central free reference library "badly," as many people think, and they might be lodged in a building and on a site "worthy of itself" if only the Infirmary trustees would sell and the money with which to buy could be found, and both these "ifs" may perhaps be got over. The retention of the infirmary in the centre as a matter of convenience in spite of smoke, smuts and traffic, or its removal to a suburb where the air is presumably somewhat less loaded with impurities, has long been a topic for argument. Of course if removed a site not too far from Owens College would be desirable. Should the removal be decided on, the question of "out-patients" next comes forward. One idea, involving a new hospital near the College and the retention of a good part of the present building for out-patients, with a few beds for accidents, may be given up as wasteful and extravagant, though at one time it seemed to be held by many. A new scheme is now brought forward, that there should be a central receiving and out-patients' department, which would constitute a medical clearing-house for the infirmary and for all the special hospitals in the city. At present no doubt there is great waste of energy both as regard staffs and patients. The Children's Hospital is at Pendlebury and its out-patient department in Gartside-street. The Consumption Hospital is at Bowdon, but the out-patients are at Hardman-street. The Eye Hospital in Oxford-street has an out-patient department in St. John-street. A building in the centre would be required large enough to accomodate all the out-patient departments of the various hospitals. Each would remain under the charge of the respective honorary staffs as at present. There would be a few beds for emergencies, while sickness and accidents would be treated there day by day and "those cases which needed to be made in-patients would be drafted out in suitable ambulances to the new infirmary, the Children's, the Eye, the Consumption, or other hospital." No doubt some economy in administration might result as there would only be one staff of officials. The arrangement is said to be simple, but it seems to be the simplicity of a Clapham-junction. And it is doubtful whether one central station would suit the out-patients from all parts of the city and suburbs as well as does the present arrangement, by which they can get treatment nearer their own doors.

The Nurse's Mistake at Crumpsall.

At the meeting of the Manchester Board of Guardians on July 13th the visiting committee of the Crumpsall Workhouse reported upon the circumstances respecting the administration by mistake of a poisonous preparation of opium. The report does not throw much light on the way in which the mistake occurred, but it states that the opiate solution was "not, in fact, left with the ordinary medicines,

Digitized by Google

but was placed in a separate locked cupboard specially used for it and the chloral mixture," and that the two bottles "are entirely different" and both labeled with the word "Caution" in red letters, and therefore that the censure passed at the inquest on Nurse Brooks was undeserved. On the other hand, the report cannot acquit Nurse Jackson, who gave the medicine, of the charge of "failing to exercise due care in the present case," but it adds that "the justice of the case has been met by the censure passed upon her by the jury." It is said, no doubt with truth, that she has suffered great mental distress and as she has not previously given any cause for complaint the report recommends that no further steps be taken in the matter. It is certainly very unlikely that she will ever again make a similar mistake. Medical men no less than the public will like to know whether she was over-tired with having been too long on duty—whether, indeed, she was overworked. It is as necessary that the administration of powerful remedies should be in the hands of a nurse who is fresh and alert as it is that the man in the railway signal-box should not be asleep.

Outbreak of Diphtheria at Urmston.

It was stated at the meeting of the Urmston District Council on July 12th that no fewer than 23 cases of diphtheria had been reported. So far the cause has not been traced. Most of the cases originated in the British schools and the infants' department has been closed. The drains of the district were said to be "in perfect condition and therefore the outbreak was not due to any drainage defect." Similarly the chairman of the sanitary committee "wished to point out most distinctly that those schools were in a perfect state of sanitation and no blame was attached to them for the epidemic." It is not always wise to be so sure. The chairman of the sanitary committee and Dr. Fryer, the medical officer of health, have been requested to inquire into the matter, and it would not be a complete inquiry if these two possible sources of mischief were left out. It may be mentioned that Urmston has its difficulties as to sewage disposal like many other places. The Urmston and Flixton joint drainage committee have a sewage farm and while the hay-making is going on the crude sewage passes directly into the Ship Canal. The joint drainage committee were summoned before the magistrates on July 7th at the Manchester police-court and fined. This imperfect mode of dealing with sewage may possibly have some bearing on the outbreak of diphtheria.

Medical Officer to the Salford School Board.

At the meeting of the Salford School Board yesterday a report was adopted recommending the appointment of a medical officer to the board at a salary of £150 per annum. Amongst other duties he would visit each department of the board schools once a year; report in writing as to the sanitary condition of the premises; examine children reported to the board as being defective or feeble-minded and decide as to their being taught at a special centre; advise the board as to the course of study, &c., of those in attendance at the centres for defective children; and examine blind and deaf children and decide whether they were suitable cases to be dealt with under the Blind and Deaf Children Act.

July 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Appointment of a Professor of Public Health in the University of Edinburgh.

AT a meeting of the University Court held on July 19th Dr. Charles Hunter Stewart was appointed to the newly-established chair of public health. The chair is named the Bruce and John Usher Chair in honour of the gentlemen who endowed it and by their munificence make it possible for the University to separate it from medical jurisprudence. Dr. Hunter Stewart is a graduate of medicine and of science of Edinburgh and has had charge of the public health laboratory for years. The University may be congratulated on having been in a position to make this important change.

The Edinburgh Meeting of the British Medical Association.

The arrangements for this meeting are practically complete and everything points to the meeting being a great success from the local, scientific, and social sides. All that is wanted is fine weather and in Scotland we can never be sure of that. The President-Elect will give an official dinner on Monday night in the Royal College of Physicians of Edinburgh. The meetings will begin on Tuesday.

School of Medicine of the Royal Colleges, Edinburgh.

At a meeting of the governing board of the School of Medicine of the Royal Colleges, Edinburgh, the secretary, Mr. R. N. Ramsay, reported that the number of students so far as ascertained attending the school during the summer session recently closed was 1239. This is a fact of much interest and shows how much extra-mural teaching is taken advantage of by university students.

University of Aberdeen.

In the medical faculty thirty-one candidates have just passed the whole of the third professional examination. Three medical graduates have after examination obtained the diploma in public health. The following have been appointed examiners for degrees and preliminary examinations: In botany, J. Reynolds Green, D.Sc. Camb., F.R.S., Cambridge; in chemistry: John Shields, D.Sc. Edin., London; in medical jurisprudence and public health: W. Leslie Mackenzie, M.A. and M.D. Aberd., medical officer of health of Leith. The appointments of university assistants to the respective professors have also been made.—The Anderson travelling scholarship, value £170, tenable for two years, has been gained by Mr. J. J. R. Macleod.

Extension of Aberdeen City Hospital.

Tradesmen's offers have just been accepted for the carrying out of additions at this hospital at a cost of about £4500. The alterations consist of additions to the administrative block to provide additional accommodation for the nurses and servants and properly-equipped discharge rooms. There will also be an addition to the diphtheria block.

Whooping-cough in Aberdeen.

The epidemic is increasing, 378 cases with 14 deaths having been reported to the local authority for a month past, as compared with 276 cases with 8 deaths in the preceding month.

Corporation Baths, Aberdeen.

The new swimming pond, 90 ft. long by 35 ft. wide, at Aberdeen sea-bathing station was opened last week. There was an aquatic gala at which a large number of medical practitioners were present. The new wing for small baths is hardly finished. The total cost to date (including half a mile of esplanade) is £12,000.

July 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Richmond District Lunatic Asylum, Dublin.

AT a meeting of the governors of the Richmond Asylum held on July 14th, the report of the resident medical superintendent, Mr. Conolly Norman, for the year 1897 was laid before the board. Referring to the fact that phthisis is the most frequent cause of death in the institution the report says: "Consumption will remain unduly frequent and mortal in the asylum until such time as there is an isolation hospital where the sufferers from this disease can be treated apart." Alluding to the serious prevalence of beri-beri during the year 1897 the report states that at the opening of the period under review 25 men and 36 women presented symptoms of the disease, which in several cases persisted during the year. Fresh cases began to come in in June so that the number before the close of the year was 238 among the patients and 8 among the staff of attendants. Besides these, the chief nurse of the infirmaries, who suffered in 1896, had a relapse of the disease in 1897.

The Medical Officers of the South Dublin Union.

At a meeting of the board of the South Dublin Union held on July 14th a memorial was read from eight medical officers of the union requesting that an increase be made in their salaries so as to raise them to the level of those paid at present to the medical officers of the North Dublin Union. The matter will be decided at the next meeting of the board of guardians.

The Royal Hospital for Incurables, Dublin.

At a meeting of the Committee of Management of this

Digitized by Google

hospital held on July 14th Mr. John Lentaigne, F.R.C.S. Irel., was coöpted a member of the committee in the room of the late Mr. Edward Fottrell.

The Infectious Diseases Hospital, Belfast.

The Public Health Committee of the Corporation have decided to postpone any action regarding the erection of the infectious diseases hospital, which they proposed to locate at Purdysburn, until after the Local Government Bill becomes law, as the position of affairs may then warrant a change in the arrangements.

The Proposed New Asylum for County Londonderry.

At a meeting of the board of governors, held on July 15th, the committee who were appointed to consider the plans for the new asylum recommended the board to accept them, the opinion of the architects being that for £110,000 the asylum can be completed. The chairman (the Right Hon. Sir Hervey Bruce, Bart., D.L.) said if the board accepted this report they would be acting illegally and the board of control would have to interfere, and another governor asked what guarantee the architects could give that the asylum could be built for the sum mentioned. The chairman (who said he looked upon the whole course pursued as perfectly illegal) and two other members of the board having left the meeting, the Mayor of Derry was moved to the chair and it was decided to adopt the plans, those opposing being of opinion that it would be wiser for a moribund board to drop the matter and leave it to the new county council.

Death of Mr. David Kilpatrick Given, L.R.C.P. Edin., L.F.P.S. Glasg.

Much regret is felt in Drumquin at the sudden death of Mr. Given, which took place at his residence there on July 16th. The deceased was dispensary medical officer of the district and was greatly beloved by his patients and very popular amongst the inhabitants of the district. The coroner having ascertained that Mr. Given's sudden death was due to heart disease did not think it necessary to hold an inquest. Mr. Given's brother is dispensary medical officer of Gortin district.

Return of another Lady Guardian in Belfast.

Miss F. F. Clarke, who was the candidate of the Society to Brighten Workhouse Infirmary Life, has been returned after a contested election for Cormac Ward, Belfast. There are now three lady guardians in the Belfast Union.

Close of the College and Hospital Session in Belfast.

The Summer Session of the Belfast Medical School has now ended both at college and at the hospitals. A large number of medical men in Belfast are going to the Edinburgh meeting of the British Medical Association, the relationship between the two schools (Belfast and Edinburgh) being a close one.

July 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hæmatozoon of Goitre.

A MEETING of the Academy of Sciences was held on July 4th, when M. Grasset gave an account of his researches among persons afflicted with goitre. Knowing the department of Puy de Dôme was that where cases of goitre were the most common he went there, and after studying the question arrived at the following conclusions. Goitre is not a local affection but a general one, with one predominating symptom—namely, an enlarged thyroid. Just as the enlarged spleen is the predominant symptom in malaria so the enlarged thyroid is the predominant symptom in goitre. There is a curious parallel also between malaria and goitre. Both have a special geographical distribution; both affect mainly a gland having an internal secretion; and in both when they reach an extreme degree cachexia supervenes—in the one case the well-known malarial cachexia and in the other cretinism. M. Grasset examined the blood from eight persons who suffered from recent goitre and was able to demonstrate the presence of a parasite. It showed in the form of spherical segmented bodies, larger in size than a red corpuscle, and recalled the hæmatozoon of malaria.

The Treatment of Lupus by Injections of Calomel.

On July 7th M. du Castel showed at the Society of Dermatology two patients suffering from tuberculous lupus of the face who had been treated during the past six months by injections of calomel after the method of Asselbergs. The good results of this treatment were very marked. M. Gaucher considered that as a rule cases of lupus cured by mercurial injections were errors of diagnosis. M. Brocq had seen in one case the mass of lupoid infiltration diminish under this treatment, but he did not know whether the result was permanent. In another case he had seen some amelioration, but afterwards the lesions remained in a stationary condition and it became necessary to attack them with the cautery; he thought, too, that the patient was syphilitic. M. Fournier was of opinion that an occasional case of wrong diagnosis might occur, but he considered that there was possible association between lupus and syphilis Anti-syphilitic treatment certainly brings about a considerable, if fleeting, improvement in cases of lingual epithelioma. Lupus in a syphilitic patient is probably seriously modified by the soil on which it grows, and this is probably the key to the results obtained by Asselbergs.

The Action of Liquid Air upon Monocellular Organisms and their Secretions.

At the meeting of the Society of Biology held on June 9th M. D'Arsonval referred to some researches which he had made with regard to the action of liquid air upon sundry tissues and upon mucous membranes. Actual contact did not take place and the substance could be introduced into the stomach. M. D'Arsonval had offered a guest some liquid air mixed with champagne and he, without waiting till the champagne thawed, swallowed the whole glassful containing about 15 c.c. of liquid air. After a few moments his stomach was acutely distended, but a sudden violent expulsion of food and gas relieved this condition. If liquid air be poured upon the hand it assumes the spheroidal state and breaks up into globules which scatter in various directions. It has been proposed to employ it in diving operations, for a diver carrying a litre of liquid air upon his back would have 1000 litres of air to breathe. M. D'Arsonval also placed in liquid air some dried bacilli and bouillon cultures of diphtheria and the bacillus pyocyaneus. In one case they were there for six days and nights until the air evaporated. He then sowed the cultures on agar and found that contrary to what he had expected the liquid air had very little effect. Growth went on regularly, the individual bacilli were slightly damaged, and the only marked modification was that the bacillus pyocyaneus had lost its chromogenic power—a modification which, of course, is not of the least importance.

Erysipelas brought on by Inoculation with Pus from a Streptococcic Empyema.

At the meeting of the Hospitals Medical Society held on July 8th M. Menetrier reported a personal observation. While dressing a patient suffering from empyema he scratched his ear, just drawing blood. Six or eight hours afterwards the ear began to smart and some days later the whole ear exhibited an acute inflammatory condition presenting all the appearances of erysipelas. The hairy scalp was invaded and the temperature rose to between 38° and 39° C. Having gone out too soon he had a relapse and this time the face was attacked, but he got well without any special treatment. Bacteriological examination of the fluid from the empyema showed that the streptococci therein were but feebly virulent. M. Nettier considers that this case bore out the experiments made in the laboratory of Koch, where it was found that to produce erysipelas in man streptococci greatly attenuated must be injected.

Removal of the Superior Cervical Ganglion for Acute Glaucoma.

At the meeting of the Ophthalmological Society held on July 5th M. Abadie showed a patient who had consulted him for acute hæmorrhagic glaucoma of the left eye and from whom he had already removed the right eye on account of the same disease. The case was one of those in which the surgeon is apparently quite powerless. The patient, after suffering intolerable agony for seventeen hours, demanded that his left eye should be removed as well. M. Abadie, however, removed the superior cervical ganglion of the left side instead and on the same evening the pain ceased. Fifteen days after this operation the condition of the eye had sensibly improved. It is therefore allowable, M. Abadie considers, in cases of this kind, where there is nothing else to do except enucleation, to remove the superior cervical ganglion. This case confirms the general theory of glaucoma—that is to say, that glaucoma is not a

Digitized by Google

vascular affection but that it springs from a stimulation of the vaso-dilators of the eye, a stimulation which goes on even to rupture. M. Valude then remarked that he had known the patient, having attended him and having performed the first operation four years ago. M. Valude had observed in these cases remissions of the same kind as had occurred in the left eye; these remissions occurred spontaneously, so to speak, but on one occasion after the application of an opium poultice. As these remissions were spontaneous or coincided with the application of domestic remedies he said that they could not definitely conclude whether the operation which M. Abadie referred to had done good or not. M. Despaguet mentioned the case of a patient who had suffered from hæmorrhagic glaucoma and had had her eye enucleated. She died from cerebral hæmorrhage, the same process having occurred in the brain which occurred in the eye. This point, he considered, was a proof of the vascular origin of glaucomatous affections.

July 19th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Anti-Rabies Institute.

IT has been proposed by some members of the public that the Government of Egypt should attach a Pasteur institute specially for rabies either to the medical school or to the hygiene institute of the sanitary department. But the Government authorities, before entertaining any such idea for the treatment of bitten folks, are doing what they can to persuade the European consuls-general of the importance of preventing the disease as far as possible. Quarantine ought to be imposed on fresh arrivals, a tax should be levied on dogs, and all stray dogs, whether native or European, should be impounded by the police and destroyed if ownerless. But for all such regulations the consent of all the Powers must be obtained, and this is no easy matter. The police in Cairo alone now kill between 2000 and 3000 stray dogs every year, but this is not enough as there are always a few wandering pariahs to be seen. It is difficult to see how any legislation can be directed against wolves, jackals, and even cats. In the early days of the British occupation there were thousands of pariah dogs in Cairo and we used to be told on all sides that rabies was unknown, but in 1886 a fox terrier at Abbassiyeh belonging to a British soldier broke the record by being the first case. Since that time every year cases among human beings or among dogs have been reported and verified. Besides many doubtful cases the whole number up to last month comprises 36 dogs, 2 wolves, 3 horses, 2 mules, and 60 human beings, all fatal, scattered over Egypt. Since 1893 several bitten people have gone to Paris or to Athens to be treated, and this year already 9 persons out of 15 bitten have gone to the Athens Institute. These figures are enough to show that preventive measures are required.

Native Remedies for Hydrophobia.

Though there are no medical accounts of rabies in times past there are plenty of supposed cures which make it appear as if the disease were well known. Papyri contain mention of the dangers of a bite from serpent, crocodile, or dog. Charms were sold in old days to protect from these three and there is a folk lore story where the wicked fairy condemned the heir at his birth to be killed by one of these three biting creatures. He destroyed a serpent who attacked him and he and his favourite hound killed a crocodile, but the master died in consequence of an accidental bite from the dog during the fight. The modern treatment for a person bitten by a presumably mad dog in Upper Egypt is to kill the dog, extract the spinal cord, bruise the cord with pestle and mortar until a paste is made, and then rub the patient's body all over with paste. Sometimes, too, they burn the dog's hair and apply the ashes to the bite. The Bedouin make the patient eat the raw liver of the dog, and this is done, too, in the Haussa State of the Western Soudan.[1] In Lower Egypt the favourite remedy has been acquired from the Syrians of Mount Lebanon. It is the *Mylabris punctata*, a dark-blue beetle used instead of cantharides and well known in the south of France and Spain. When taken by the patient it produces strangury, and the old women pretend that if the dog be mad the patient's urine will contain dog-like growths each of about the size of a barleycorn.

The Assuan Reservoirs.

The latest news from Assuan tells of a shade temperature of 124° F. beating on the rocks and of the death from sunstroke of an Englishman there. He was superintending the 800 men who are already working for the future reservoirs. Next winter there will be ten times as many labourers and many European inspectors, all of whom will require medical help.

Veterinary Report for Alexandria.

The municipality in its annual report draws attention to the fact that out of 116,439 animals killed in the slaughter-house during 1897 nearly half came from foreign ports, such as Tripoli, Syria, Russia, and Cyprus. This is one of the reasons why quarantine measures have to be strict for all cattle arriving in Egypt, and all entry of Syrian cattle has now been forbidden in consequence of the numerous cases of rinderpest. Several ideas are to be carried out for the better inspection of meat in the town and also for its local transport and a scheme has been approved for cooking at the slaughter-house itself meat which by reason of its parasites is dangerous for consumption only in its raw state. 39 horses and 4 mules suffering from glanders were killed during the year and great praise is given to the use of mallein, which was injected into 197 horses. During the present year it is intended to inject all the horses, mules, and donkeys in Alexandria with mallein to stamp out glanders entirely. The veterinary surgeon has proposed some very stringent laws with regard to tuberculosis of animals and compulsory inoculation of all cows with tuberculin, but these measures have not been adopted by the municipality.

Work at the Barrage.

Two additional weirs across both the Damietta and Rosetta branches of the Nile have now been begun, though, of course, the work can only be carried out during low Nile. Half a million pounds are to be expended, and besides strengthening the two barrages the new weirs will allow 5 ft. extra of water to be held up for the benefit of the three important canals which branch off from the barrage to the Delta. It is calculated that this will make no practical difference to the velocity of the Nile at Cairo, which is already reduced by the barrage from nine miles to seven miles a day during the month of lowest Nile. This year's Nile is late and bids fair to be a poor one.

Cairo, July 6th.

[1] See THE LANCET, May 18th, 1895, p. 1274.

Obituary.

DUNCAN JAMES CADDY, M.D. DURH., F.R.G.S.

DR. CADDY, who died at his residence, 4, Earl's Court-gardens, S.W., on July 5th, was educated at the Merchant Taylors' School. Leaving there he proceeded to King's College, London, where he entered as a medical student in 1889. He graduated at Durham University in 1892 and took his degree as Doctor of Medicine in 1894. In the same year he was elected a Fellow of the Royal Geographical Society. Subsequently Dr. Caddy joined H.M. Colonial Medical Service and did good service in the West Indies. During his appointment there, at a great risk of his life, he saved a native from drowning and afterwards received from the Royal Humane Society its bronze medal for his gallantry. He was kind and courteous to all his patients, respected by everyone who knew him, ever anxious to help all and greatly esteemed. His death at an early age cuts short the promise of a brilliant career.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Hugo Gerold, formerly Professor in the University of Giessen, a post which he subsequently exchanged for a large practice in Gotha. Since his retirement he has been in Halle, where he died at an advanced age, having graduated in 1835. He was a frequent contributor to medical literature, especially on ophthalmic topics.—Dr. Ernst Candèze, Superintendent Physician of the Glain Lunatic Asylum near Liège, who was well known in scientific circles on account of his numerous original papers on entomology.—Dr. Page, Professor of Medicine in the New York Polyclinic.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE. — *Berlin*: Dr. Victor Meyer has been recognised as *privat-docent* of Laryngology.—*Bonn:* Dr. Heinrich Walb has been promoted to an Honorary Professorship of Otology.—*Gratz:* Dr. Victor Fossel has been appointed Extraordinary Professor of the History of Medicine.—*Leipsic:* Dr. Martin Ficker has been recognised as *privat-docent* of Hygiene and Bacteriology. —*Moscow:* Dr. Pokrovski has been recognised as *privat-docent* of Pathological Anatomy.—*Odessa:* The organisation of the newly-established medical faculty has been entrusted to Dr. Podvisotski, Professor of General Pathology in Kieff, who is to be the first Dean of the Odessa Medical Faculty.—*Padua:* Dr. Dante Cervesato has been promoted to the Ordinary Professorship of Children's Diseases.—*Prague:* Dr. Ivan Honl, Assistant in the Bohemian Institute for Pathological Anatomy and Bacteriology, has been recognised as *privat-docent* of Bacteriology. — *Vienna:* Dr. Alexander Kolisko, Extraordinary Professor of Pathological Anatomy, has been promoted to the Ordinary Professorship of that subject in succession to the late Dr. M. E. von Hofmann; Dr. Rudolf Gruber has been recognised as *privat-docent* of Ophthalmology.

SWANSEA HOSPITAL. — The report of the Swansea Hospital for the year ending March 31st, 1898, shows that the expenditure during the year was £5159 and the income £4634. The deficiency at present amounts to £525. The report adds that the building is too small for the number of patients and that £2845, derived from the Guesdon Trust, has been spent upon improvements, including the heating of the operating theatre.

THE DENTAL HOSPITAL OF LONDON. — The annual conversazione and prize distribution connected with this institution was held at the Royal Institute Galleries, Prince's Hall, Piccadilly, on Tuesday last. The Right Hon. Lord Ludlow delivered an interesting though somewhat discursive address on scientific advance during the Victorian era with special reference to surgical and dental progress. The noble and learned lord held that surgical science had outstripped medical science in the race, and that the refinements of modern dentistry might trace ither birht to the time of the discovery of antiseptics and anæsthetics. The evening concluded with an interesting musical entertainment.

THE LONDON HOSPITAL MEDICAL COLLEGE.—Mr. Douro Hoare, chairman of the College, on Monday last distributed the following prizes: Price Scholarship in Science (£120), Mr. J. Jones. Price Scholarship in Anatomy and Physiology (£60), Mr. R. Warren. Entrance Science Scholarships: £60 scholarship, Mr. R. V. Dolbey; and £35 scholarship, Mr. T. Williams. Buxton Scholarships—Arts: £30 scholarship, Mr. M. Culpin; and £20 scholarship, Mr. G. Rodolph. Clinical Medicine: £20 scholarship, Mr. A. F. Tredgold; honorary certificates, Mr. W. E. Heilborn and Mr. C. White. Clinical Surgery: £20 scholarship, Mr. R. Howard and Mr. G. R. Slade (equal, scholarship divided); honorary certificates, Mr. E. Frazer and Mr. C. Pike. Clinical Obstetrics: £20 scholarship, Mr. J. Sherren; honorary certificates, Mr. R. C. B. Wall and Mr. D. J. Thomas. Andrew Clark Prize: honorary certificates, Mr. R. C. B. Wall, Mr. A. F. Tredgold, and Mr. C. White.

ROYAL VICTORIA COTTAGE NURSING HOME.—On July 12th the Duchess of Albany opened at South Ascot a new parochial institution which has been erected as a memorial of the Queen's Diamond Jubilee and has been named, by permission, the Royal Victoria Cottage Nursing Home. It serves the double purpose of a cottage hospital and a home for parish nurses employed on the Holt-Ockley system, by which patients contribute according to their means towards the cost of their nursing in time of illness. The originator of the movement is Mrs. Liddell, widow of the late Dr. Liddell, Dean of Christchurch and author, together with Dean Scott, of the well-known Greek Lexicon. Part of the site was given by the late General Crutchley and the other half by Dean Liddell. The building has been erected at a cost of about £2200, the architect being Mr. William Menzies, of Englefield Green, Surrey. It contains three wards and accommodation for seven nurses. The medical staff consists of Dr. G. E. Barron, Dr. A. G. Paterson, and Mr. A. G. Lacy.

DEVON COUNTY ASYLUM.—Dr. G. J. Symes Saunders has just resigned the post of resident physician and medical superintendent of the Devon County Lunatic Asylum, Exminster, Exeter, which he has held for nearly forty years, succeeding the late Sir John Bucknill, M.D. The appointment rests with the Devon County Council.

BEQUESTS AND DONATIONS TO HOSPITALS.—The committee of the Westminster Hospital has received £300 from the trustees of Smith's (Kensington Estate) Charity.—The committee of the City of London Hospital for Diseases of the Chest, Victoria Park, has received £105 from Messrs. Charrington and Co.; also £200 from the trustees of Smith's (Kensington Estate) Charity; also £155 from the employés of the Great Eastern Railway Company.—The committee of the North-West London Hospital, Kentish-town-road, has received £200 from the trustees of Smith's (Kensington Estate) Charity. —The committee of the North London, or University College, Hospital, Gower-street, has received £100 from Mr. Samuel Mills.—A donation of £1000 has been received by the committee of the King's College Hospital, London, for endowment of a bed in memory of the late Mr. H. P. Vulliamy.

DIPHTHERIA IN LONDON.—In the two weeks ended on Saturday, July 9th, the registered deaths from diphtheria in London continued to be considerably under the corrected decennial averages for the particular weeks. In the former, ended on July 2nd, the recorded deaths numbered 29, following upon 23, 26, and 21, the respective totals of the three weeks preceding. The corrected average for the corresponding week of the years 1888-97 was 37 deaths. All the 29 deaths were of young people under twenty years of age, 16 being of children aged under five years, of whom 3 were infants. Poplar was credited with 4 deaths. The close of the week found 976 diphtheria patients still under isolation in London hospitals, the admissions in the week having been 120, against 130, 134, and 126 in weeks immediately preceding. In the Outer Ring there were registered 11 diphtheria deaths, of which 3 occurred in West Ham district. In the succeeding week the registered deaths from the disease in London were 27 in number, being as many as 13 below the corrected decennial average. Five belonged to Poplar and 3 to Shoreditch parish. All the deaths were of young persons aged under twenty years, of whom 16 were children aged under five years, 4 being infants. In the Outer Ring there were 10 deaths registered from the disease, 4 belonging to Hendon and 3 to West Ham districts. Last week the registered deaths from the disease in London rose again, the number having been 39, of which all but one were of persons aged under twenty years, 24 being of children under five years of age. Five deaths belonged to Lambeth, and 4 each to St. Pancras and Islington. In the Outer Ring 9 deaths were registered, of which 3 occurred in Richmond and 3 in Hendon registration districts.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL. The presentation of scholarships, medals, prizes, and certificates took place at this school on Wednesday last, Mr. T. McKinnon Wood, the chairman of the London County Council, presiding. Dr. Montague Murray, the Dean of the school, in submitting his report took occasion to refer to the appointment of Mr. Mackenzie Davidson to the superintendence of the Roentgen ray department and to the resignation of Dr. Watt Black, who has been lecturer on midwifery for twenty-nine years and treasurer of the school for eight years. He has been succeeded in his lectureship by Dr. Amand Routh and in the treasurership of the school by Mr. J. H. Morgan. During the year a new bacteriological laboratory had been opened. A recreation ground had been presented to the students club by Mr. E. J. Churchill. Attention was also directed to the many useful societies organised by the students, and the past academic year was a satisfactory record of successes in the examination room. The report closed with the announcement, which has already appeared in our columns, that Professor Virchow had consented to open the next winter session with the delivery of the second Huxley Lecture, which had been founded three years ago to commemorate the fact that Huxley had received his medical education at Charing-cross

Digitized by Google

Hospital. On the occasion referred to the chair will be taken by Lord Lister, P.R.S. Mr. McKinnon Wood having presented the prizes addressed the students in suitable terms. He congratulated them on their success. Referring to the work of the London County Council he pointed out that in one direction their aims were one and the same with the medical profession. Both combined to diminish the death-rate. He referred also to the interest taken by the council in two points of view of hospital work—that of the care of poor patients and of the educational value of such institutions to the medical profession. Sir Joseph Fayrer proposed a vote of thanks to the chairman, which was seconded by Mr. Morgan. The Llewellyn prize, the governor's gold medal, and the senior prizes for medicine, surgery, practical midwifery, and public health were awarded to Mr. P. L. Daniel. Mr. E. F. Ackery secured the Huxley medal, Mr. S. A. Boyd the Golding prize, and Mr. E. L. Lilley the Pereira prize.

BRISTOL AMATEUR DRAMATIC WEEK. — The accounts in connexion with the recent amateur week at the Prince's Theatre, Clifton, in aid of the Bristol medical charities show that, although £487 were taken as a result of the performances, after paying all expenses only £36 10*s.* remained to be divided amongst the charities.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The General Medical Council and Unqualified Assistants.

MR. LOGAN has given notice of the following question for Tuesday, July 26th, viz.:—"To ask the First Lord of the Treasury if he is aware that in December last the General Medical Council passed a resolution disapproving of the employment by medical men of unqualified assistants, in consequence of which a large number of such assistants who have been trained for the medical profession, many of whom have families, are and will be deprived of the means of obtaining a livelihood; and if there are any means whereby he can intervene and provide that those now or recently so employed shall be permitted to continue their vocation."

HOUSE OF COMMONS.

THURSDAY, JULY 14TH.

Lead-poisoning in the Potteries.

Mr. DRAGE asked the Home Secretary whether he could give any statistics showing the effect of employment in the dangerous processes in potteries on the health of women and their children as well as on the health of young persons.—Sir M. WHITE RIDLEY: I am not aware what kind of statistics the hon. Member has in his mind. There are many recorded instances which amply prove that in the pottery trade, as elsewhere, the occurrence of lead-poisoning in the mother is capable of producing grave effects upon the child. The total number of recorded cases of lead-poisoning among women and girls engaged in the manufacture of earthenware and china during the two and a half years since the Act of 1895 came into force is: women, 528; girls, 63—a yearly average of about 230. The number of females employed in Staffordshire was 20,705.—Mr. DRAGE asked the right hon. gentleman whether he could give any statistics comparing the health of workpeople in potteries where mechanical ventilation has been introduced with the health of workpeople employed in potteries without mechanical ventilation.—Sir M. WHITE RIDLEY: I am afraid I have no statistics of the kind and it would be difficult to obtain them. The great improvement effected by the introduction of mechanical ventilation is sufficiently evident, and one of the points aimed at in the new rules I am taking steps to establish is the more general adoption of fans in all dusty processes in potteries.—Mr. WOODALL: May I ask the right hon. gentleman whether he will consider the practicability of informing the House as to the proportion of cases in which lead-poisoning has been certified by a medical practitioner whose report has afterwards been found to be unfounded?—Sir M. W. RIDLEY: Every information of that kind I am now endeavouring to obtain. It is a very difficult question, but I will bear it in mind.

Tuberculosis.

Mr. CHANNING asked the President of the Board of Agriculture whether he had considered the Report of the Commission on Tuberculosis as regards the successful adoption of the policy of gradual elimination of tuberculosis by the use of the tuberculin test in Denmark and elsewhere; whether he would take steps to carry out the recommendation of the Commission that properly prepared tuberculin and the services of veterinary surgeons should be provided by the State to enable agriculturists in this country to adopt the policy of elimination; and whether he would apply to the Treasury to sanction the small grant of £5625 per annum which the Commission think sufficient to initiate this policy.—Mr. WALTER LONG: I am afraid that as yet I can add nothing to what I said in reply to the question addressed to me on this subject in April last, except that since that time the report of the Royal Commission has been fully considered by the Central Chamber of Agriculture and that no desire whatever was then manifested for the provision of facilities for the application of the tuberculin test. It is clear, I think, that I could not approach the Treasury on the subject with any hope of success until there is evidence that agriculturists really wish that their cattle should be subjected to the proposed test on the conditions suggested by the Commission.

Gallant Conduct of Surgeon-Lieutenant Hugo.

Sir WALTER FOSTER asked the Secretary of State for India whether his attention had been called to the gallant conduct of Surgeon-Lieutenant Hugo, of the Malakand Field Force, under the following circumstances:—Lieutenant Ford was dangerously wounded in the shoulder and was bleeding to death from the bullet having cut the main artery when Surgeon-Lieutenant Hugo came to his aid. The fire was too hot to permit lights to be used to examine the wound and there was no cover, nevertheless, the surgeon struck a match and examined the wound. The match went out amid a splutter of bullets, which kicked up the dust all round, but by its uncertain light he saw the nature of the injury and seized the bleeding artery and, as no ligature was available, he remained for three hours under fire holding the vessel between his finger and thumb. When at length it seemed that the enemy had broken into camp he picked up the officer, who was unconscious from loss of blood, and bore him into a place of safety without relaxing his hold of the artery; and whether the authorities had taken steps to reward suitably this splendid act of devotion.—Lord GEORGE HAMILTON: The officer who performed the gallant action referred to in the question was Surgeon-Lieutenant J. H. Hugo, who for his services in the late campaign has received the decoration of the Distinguished Service Order.

The Hospital at Aden.

Mr. MOON asked the Secretary of State for India whether any English nurses had been engaged for the hospital at Aden; and whether the Government of India or the Admiralty would pay their salaries.—Lord GEORGE HAMILTON: I am not aware whether any British nurses have yet been engaged for the hospital at Aden, but I am in communication with the Government of India on this subject, as also regarding the proportion of their salaries to be paid by the Admiralty and Port funds respectively. The latter point to a large extent regulates the class of nurses to be engaged.

Prosecutions for Illegal Operation.

Mr. PICKERSGILL asked the Attorney-General, with reference to the recent trial of Dr. Collins at the Central Criminal Court on an indictment for wilful murder, when the Attorney-General, who prosecuted for the Crown, while presenting the death as due to a felonious act done by the prisoner, invited the jury to return a verdict of manslaughter only, and they accordingly did so, whether, with a view to regularise such verdicts, he would consider the propriety of introducing an amending Bill, so that a person who without an intention to injure kills another by a felonious act not likely in itself to cause death or grievous bodily harm may be regularly convicted of manslaughter and not of murder.—The ATTORNEY-GENERAL (Sir RICHARD WEBSTER): In my opinion there is no need for any such amending Bill. The law, as I endeavoured to express it on the occasion to which the hon. Member refers, has been laid down more than once by distinguished judges in charging the jury.

FRIDAY, JULY 15TH.

Yellow Phosphorus in the Match Trade.

Mr. STEADMAN asked the Home Secretary if he would inform the House what steps he was taking to inquire into the deadly use of yellow phosphorus in the match making trade, and, if so, would he report the result of such inquiries at the earliest opportunity.—Sir M. WHITE RIDLEY: The steps taken are, very briefly, these: every match factory in the country has been specially visited and reported on by the factory inspectors; many of them also, so far as the employment of women is concerned, by the lady inspectors. Inquiries are being made through the Foreign Office as to the measures adopted and results obtained in foreign countries. Further, the question is being investigated on the scientific side by two distinguished experts—Dr. Oliver and Dr. Thorpe—the former of whom has already visited the chief match factories in France and made a special report; and from the dental point of view by Mr. George Cunningham, dental surgeon of the London Hospital, who has already made a preliminary report, and whom I propose to send to France to continue his inquiries in the French manufactories. I shall as soon as possible communicate to the House the result of these investigations.

The Case of Dr. Lynch of Walsall.

Mr. SYDNEY GEDGE asked the First Lord of the Treasury, as representing the Lord Chancellor, on what grounds and on whose recommendation a medical practitioner at Walsall named John Joseph Lynch has recently been made a magistrate of that borough, the following statement of facts respecting Dr. Lynch having been on the 5th instant admitted by the Home Secretary to be correct—viz., that Dr. Lynch did in December last certify that a boy named William Charles Young died from natural causes although he had not seen the boy for a month before his death and another doctor had attended him in his last illness; that on the inquest the jury found that the boy had died from swallowing a halfpenny, and that, in consequence of this and of a further representation made to the Registrar-General officially by the town clerk of Walsall, the Registrar-General directed the superintendent-registrar there to treat all certificates given by Dr. Lynch of deaths from natural causes as equivalent to certificates of death with a view to his holding inquests in such cases; and was the Lord Chancellor aware that Dr. Lynch was under this stigma when he was selected as worthy to be placed on the judicial bench; and whether, now that his lordship's attention had been called to the fact, he would take steps to remove Dr. Lynch from the bench.—Mr. BALFOUR: I am informed by the Lord Chancellor that, following out the principles observed by all his predecessors, he thinks it is undesirable to state the grounds for any appointment to the bench or the sources of information on which it is made further than to state that he has satisfied himself as to the facts on authority in which he has entire confidence. If any facts are brought to his notice establishing *prima facie* any misconduct on the part of Dr. Lynch the Lord Chancellor will, in accordance with the usual practice, inquire into them and give Dr. Lynch an opportunity of explanation.—Mr. SYDNEY GEDGE: The last part of the question has not been answered—whether the Lord Chancellor was aware of the stigma that

Digitized by Google

rested upon Dr. Lynch when he made the appointment and whether, now that his lordship's attention has been called to the matter, he will take steps to remove Dr. Lynch from the bench. I may add that the appointment is causing great agitation.—Mr BALFOUR: I have no information as to the state of the Lord Chancellor's information when he appointed Dr. Lynch. The last question I have already answered.

MONDAY, JULY 18TH.

Army Medical Service.

Captain NORTON asked the Under Secretary of State for War whether he could state if officers of the Army Medical Staff were obliged to retire at an earlier age than combatant officers although they entered the army several years older on an average; whether the rule regarding promotion to the rank of major-general had been applied to medical officers to the extent that they were ineligible for promotion after attaining the age of fifty-seven years; and why the rule permitting all major-generals to serve on to sixty-two was not also made applicable to all surgeon-generals, seeing that such an extension of service would be economical to the State.—Mr. BRODRICK replied: In the combatant ranks colonels retire at fifty-seven years of age and major-generals at sixty-two. In the Army Medical Staff the age of sixty holds for both ranks. The medical officers have therefore the advantage of three years in one rank while they lose two years in the other. Medical officers are not ineligible for promotion to the rank of surgeon-general after the age of fifty-seven if recommended by the Promotion Board as possessing exceptional abilities. As a general rule, however, promotion to the rank of surgeon-general is only given to officers who have at least three years to serve. The Secretary of State is advised that having regard to all the conditions involved it would not be desirable to extend the rule under which major-generals are allowed to serve on to sixty-two to all surgeon-generals.

Habitual Inebriates Bill.

This Bill, as amended by the Grand Committee on Law, was considered and on the motion of the Home Secretary a new clause was inserted giving power to recover expenses against the estate of the inebriate. Thereafter the Bill was read a third time.

TUESDAY, JULY 19TH.

The Physic Garden at Chelsea.

Mr. WHITMORE asked the honourable Member of the Thirsk Division of Yorkshire, as a Charity Commissioner, whether he was aware that the Society of Apothecaries had resolved that it could no longer maintain the Physic Garden at Chelsea, and whether, in view of this decision and in order to preserve this ancient garden, the Charity Commission would be willing to sanction its acquisition by the governing body of the City Parochial Charities and its subsequent maintenance by them as a botanical garden.—Mr. GRANT LAWSON, in reply, said that the Society of Apothecaries as trustees of the Physic Garden at Chelsea, had applied to the Charity Commissioners for the establishment of a scheme for the future administration of the trusts regulating the garden which was now maintained at the charge of their corporate funds and they desired to be relieved from the trusteeship. The Commissioners had received from the trustees of the London Parochial Charities an offer to undertake the trusteeship of the garden and to make a provision for its maintenance for the purpose of botanical study which appeared to be sufficient for the purpose. The Commissioners accordingly proposed to publish a scheme giving general effect to these proposals.

The General Medical Council and Irregular Practice.

Dr. FARQUHARSON asked the Chancellor of the Exchequer whether, having regard to the fact that a sum of £5000 a year of public money was paid to the council of the Incorporated Law Society to assist them in purifying the legal profession, he could see his way to make a similar grant to the General Medical Council to enable them to undertake the prosecution of irregular medical practitioners.—Sir MICHAEL HICKS-BEACH replied that the sum of £2500—not £5000—was voted to the Incorporated Law Society for this purpose. It was a very small fraction of the yield from the special duty on solicitors' certificates which went to the Exchequer. No such tax was imposed upon medical practitioners and therefore no question of a similar grant arose.

Accommodation for Epileptics.

Sir MANCHERJEE BHOWNAGGREE asked the President of the Local Government Board when the arrangements for providing further accommodation for imbecile children who are epileptic, which were stated by him recently to be under the consideration of the Metropolitan Asylums Board, were likely to be completed and whether he was taking any steps to provide such accommodation for emergent cases pending the completion of the arrangements.—Mr. CHAPLIN: The arrangements which the managers of the Metropolitan Asylum District have under consideration for providing further accommodation for imbecile children who are epileptic are dependent on their acquiring the buildings of the South Metropolitan School District at Sutton. Negotiations for this purpose are in progress, and I believe are proceeding satisfactorily. It will devolve on the guardians to provide for the cases of children of the class referred to who may become chargeable on the rates when they cannot be admitted to the asylums of the managers.

The Vaccination Bill.

On the question that the Vaccination Bill as amended by the Grand Committee on Law be now considered, Mr. PICKERSGILL moved as an amendment that it be considered on this day six months. He and several members who think with him delivered speeches condemning the measure as a whole, but after a time they withdrew the amendment and allowed the consideration of the Bill to proceed.

Sir WALTER FOSTER moved to insert as a new clause the following, viz.:—"Where a child is by the Act required to be vaccinated within six months from the birth of the child, the parent or person having the custody of the child may, not less than two months before the expiration of six months from the birth of the child make a statutory declaration of conscientious objection to the vaccination of the child, before not less than two magistrates in petty sessions, and if the statutory declaration is within seven days after its date delivered to the vaccination officer for the district in which the child resides the vaccination officer shall register the same and shall, if required, deliver to the parent or other person making the declaration a certificate of such registration, and thereupon an order shall not be made or proceedings taken with reference to the non-vaccination of the child mentioned in the certificate." He pleaded, as he did before the Grand Committee, that such a provision as this for conscientious objection was in the interests of vaccination, being calculated to get rid of the "vaccination martyr" and reduce irritation and agitation throughout the country.

Mr. CHAPLIN opposed the clause.

Sir WILLIAM HARCOURT and Colonel LONG spoke in its support.

Sir WILLIAM PRIESTLEY said he could not vote for it because he regarded it as tantamount to abolishing compulsory vaccination altogether.

Dr. FARQUHARSON supported the clause, saying that the Parliamentary Bills Committee of the British Medical Association, which represented the boiled-down Parliamentary wisdom of the profession, favoured it.

Dr. CLARK also spoke in favour of the clause.

After the debate had gone on for several hours Mr. BALFOUR addressed the House. He suggested as a means of sifting out the genuine objector and distinguishing him from the sham one—the aim which they all had in view—that it should be regarded as a complete defence if a parent when brought before the court could show that he had genuine and conscientious objections to the process of vaccination. He should ask the House, if it was prepared to accept that view, to make the experiment only for five years, because great weight ought to be attached to the report of the Commissioners, who, while advising unanimously that penalties should be abandoned in the case of the conscientious objector, were so conscious that the experiment might prove a perilous one that they suggested that it should be temporary in its operation. The form of clause he would propose was: "No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Act of 1867 if he satisfies the court that he conscientiously believes that vaccination would be prejudicial to the health of the child and that the failure to have the child vaccinated has been and is due solely to such conscientious belief on his part." There would be a subsection: "Proceedings under the said Section 31 shall be taken only once in respect of the same child, and not until such child shall have attained the age of four years." Then at the end of Clause 10 he should add these words: "The Bill shall remain in force until Jan. 1st, 1904." He put this proposal forward as a compromise and he hoped it would be accepted by the House.

Sir WILLIAM HARCOURT suggested that members should have a little time to consider the exact effect of the proposal.

With this object the debate was adjourned until the following day.

WEDNESDAY, JULY 20TH.

The Vaccination Bill.

When the House resumed consideration of the Vaccination Bill Sir WALTER FOSTER withdrew his proposed new clause and the debate proceeded on the following clause proposed by Mr. CHAPLIN—viz.: "No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act of 1867 if within four months from the birth of the child he satisfies two justices in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child, and within seven days thereafter delivers to the vaccination officer for the district a certificate by such justices of such conscientious objection."

Objection was taken to the word "satisfies" and the proposal was made to substitute for it "makes a statutory declaration before," but when pressed to a division it was rejected by 158 to 101 votes and the clause as moved by Mr. Chaplin was adopted.

Dr. CLARK moved to insert a provision that the vaccination should be "with such lymph as the parents may desire." The Government refused to accept it and in the end it was negatived without a division.

On the motion of Mr. CHANNING words were inserted to provide for the postponement of vaccination in a district where there was or had been a prevalence of infectious disease.

The clause introduced in the Grand Committee on the motion of Sir William Priestley with regard to the dissemination by local authorities of vaccination literature was struck out of the Bill by 270 to 49 votes. The only other alteration of importance made was the insertion of a provision confining the operation of the Act to five years. The third reading of the Bill was postponed.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ARTHUR, H., M.D., C.M. Glasg., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Airdrie District of Lanarkshire.

BAILEY, FRANCIS WILLIAM, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Anæsthetist for the Royal Infirmary, Liverpool.

BATE, G. P., M.D. Brux., F.R.C.S. Edin., M.R.C.S., of Hackney, has been appointed Medical Referee under the Workmen's Compensation Act, 1897, for the County Court District No. 40.

COLLEN, GEORGE DENBIGH, M.A., M.D., M.B., B.Ch. Dubl., has been appointed Medical Officer for the All Saints' District, Northampton Union.

CRAWFORD, J. D., L.R.C.P., F.R.C.S. Edin., M.R.C.S., of Liverpool and Freshfield, has been appointed a Medical Referee for the district including the County Court of Liverpool.

DOBBIN, F. W., M.D., B.Ch. Dubl., has been appointed Medical Officer of Health by the St. Albans Rural District Council.

DUNWOODY, W. G., M.D., B.S. Dubl., has been appointed Medical Officer for the Downham Sanitary District of Ely Union.

ELKINS, F. A., M.D., C.M. Edin., has been appointed Medical Superintendent for the Leavesden Asylum of the Metropolitan Asylum District.

NICHOLSON, C. R., L.R.C.P., M.R.C.S., has been appointed Senior House Surgeon for the Hastings, St. Leonard's, and East Sussex Hospital, vice H. C. T. Langdon, resigned.

RICHARDSON, W. P., M.B., C.M. Edin., has been appointed a House Surgeon for the Hospital for Sick Children, Newcastle-on-Tyne.

ROSS, J. A., M.B., C.M. Aberd., has been appointed Medical Officer for the Workhouse of the Penistone Union.

ROUTH, A. J. M., M.D. Lond., B.S., M.R.C.P., M.R.C.S., has been appointed Obstetric Physician to the Charing-cross Hospital, vice W. Black, resigned.

SMITH, W., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon to the Walsall and District Hospital, vice Dr. Nixon.

SMITH, W. E., M.B., C.M. Edin., has been appointed Junior House Surgeon to the Royal London Ophthalmic Hospital, Moorfields, E.C.

STEWART, C. H., M.B., C.M. Edin., D.Sc., B.Sc., has been appointed to the Professorship of Public Health and Sanitary Science at the Edinburgh University.

STUART, J. A. ERSKINE, L.R.C.P. & S. Edin., has been re-appointed Medical Officer of Health and Superintendent of Infectious Hospital for the Borough of Batley.

THOMSON, ST. CLAIR, M.D., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed a Physician to the Throat Hospital, Golden-square, London.

THORNE, MAY, L.S.A. Lond., M.D. Brux., has been appointed a Clinical Assistant for the Royal Free Hospital, Gray's-inn-road, London.

WATT, J. R., M.B., C.M. Glasg., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Sheriffdom of Ayr.

WALKER, S., M.R.C.S., of Middlesborough, has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County Court Circuit No. 15.

WHITFIELD, ARTHUR, M.D., M.R.C.P., M.R.C.S., has been appointed Physician for the Skin Department of the Great Northern Central Hospital, Holloway-road, N.

WHITTINGTON, THOMAS PRICE, L.R.C.S., L.R.C.P., L.M. Edin., has been re-appointed Medical Officer of Health for Neath, Glamorganshire.

WILSON, T., M.D., F.R.C.S., has been appointed Medical Officer for the infirmary of the parish of Birmingham.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £60, with board and washing.

BETHLEM ROYAL HOSPITAL, Lambeth-road, London, S.E.—Second Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments in the hospital, complete board, and washing. Applications to the Clerk, Bridewell Hospital, New Bridge-street, E.C.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

CARDIFF INFIRMARY.—Assistant House Physician and Assistant House Surgeon for six months. Salary at the rate of £50 per annum, with board, washing, and apartments.

CHARING-CROSS HOSPITAL, London.—Assistant Anæsthetist.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. The post is tenable, subject to annual re-appointment, for three years. Honorarium 20 guineas per annum.

COUNTY ASYLUM, Dorchester.—Second Assistant Medical Officer. Salary commences at £130, rising to £160.

DERBY COUNTY HOSPITAL.—Second Assistant Medical Officer, unmarried. Salary £100 per annum, rising to £120, with board, lodging, and washing. Applications to B. S. Currey, Esq., St. Michael's Churchyard, Derby.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Assistant House Surgeon for twelve months. Salary £40, with board, residence, and washing.

DUNDEE ROYAL INFIRMARY.—Two Resident Medical Assistants for six months. Salary at the rate of £40 per annum, with board and washing.

HOLBORN UNION.—Resident Medical Officer for the Workhouse, Shepherdess-walk, City-road, N., unmarried or widower without children. Salary £200 per annum (to include midwifery fees if called upon to act), with furnished apartments, gas, coal, washing, and attendance, fees for vaccination and 10s. 6d. in respect of each certificate under the Lunacy Act. The appointee will be required to pay £60 per annum towards the cost of his rations. The appointment is subject to statutory deductions. Applications to the Clerk to the Guardians, Holborn Guardians' Offices, Clerkenwell-road, E.C.

HOSPITAL OF ST. FRANCIS, 145, New Kent-road, London.—Orthopædic Surgeon and Ophthalmic Surgeon.

LAMBETH INFIRMARY.—Resident Clinical Assistant and Second Assistant to the Medical Superintendent for six months. Salary at the rate of £50 per annum. Applications to the Medical Superintendent, Brook-street, Kennington-road, S.E.

LONDON SCHOOL OF MEDICINE FOR WOMEN, Handel-street, Brunswick-square, W.C.—Demonstrator in Physiology.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence in the institution.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officer at the Park Fever Hospital, Hither Green, Lewisham, S.E., unmarried. Salary £160 first year, £180 second year, and £200 the third and subsequent years of service, with board, lodging, attendance, and washing, subject to statutory deduction. Applications to the Office of the Board, Norfolk-street, Strand, W.C.

NOTTINGHAM GENERAL DISPENSARY.—Senior Resident Surgeon. Salary £180 a year, increasing to £200 by £10 a year, subject to board expenses. Also Clinical Assistant for six months. Salary £60.

OWENS COLLEGE, Manchester.—An Additional Demonstrator of Anatomy for the ensuing winter session.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

ROYAL SEA-BATHING HOSPITAL, Margate.—Resident Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary, R.S.B. Hospital Offices, 30, Charing-cross, London.

SALFORD SCHOOL BOARD.—Medical Officer. Salary £150 per annum. Applications to the Clerk to the Board, School Board Offices, Salford.

SALISBURY INFIRMARY.—Assistant House Surgeon for six months. Honorarium of £10 will be given conditionally. Board, lodging, and washing provided.

SCHOOL BOARD FOR LONDON. Lecturers. Application to the Clerk of the Board, Victoria-embankment, W.C.

SUSSEX COUNTY HOSPITAL, Brighton.—House Physician, unmarried. Salary commencing at £50 per annum, with board and residence in the hospital.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, Cardiff. Assistant Lecturer and Demonstrator in Anatomy. Stipend £120 per annum. Also Temporary Assistant Lecturer and Demonstrator in Physiology for one year. Salary £120. Applications to the Registrar, University College, Cardiff.

UNIVERSITY OF ST. ANDREWS, St. Andrews.—Professors of Materia Medica and Pathology to conduct classes at Dundee.

WESTERN GENERAL DISPENSARY, Stafford-street, Marylebone-road, London.—House Surgeon, unmarried. Salary £60, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

CLARK.—On July 13th, at Wilton-place, Ilkeston, the wife of David Y. Clark, L.R.C.P., L.R.C.S. Edin., of a son.

DICKINSON.—On July 16th, at Milverton-terrace, Leamington Spa, the wife of George Dickinson, M.R.C.S., L.R.C.P. Lond., of a son.

JAMES.—On July 16th, at Barton House, Beverley, Yorkshire, the wife of Surgeon-Lieutenant-Colonel James, of a daughter.

KEOGH MURPHY.—On July 17th, at Princes-square, W., the wife of J. Keogh Murphy, M.B. Camb., L.R.C.P. Lond., M.R.C.S., of a son.

MARRIAGES.

ALEXANDER—MILLAR.—On July 19th, at the Cathedral Church of St. Mary, Edinburgh, William Gordon Alexander, M.B., C.M., Stalbridge, to Katrina Louisa Hoyer, daughter of the late Christian Hoyer Millar, of Blair Castle, Culross, N.B.

APPLEYARD—HARRIES.—On June 13th, at the Court House, Umtali, Rhodesia, Francis Edward Appleyard, B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., elder son of George Appleyard, Halifax, to Beatrice Louise, youngest daughter of Barret Harries, of Byfleet, Surrey.

RICHARDSON—TONKING.—At Camborne Parish Church, on July 16th, Adam Richardson, M.B., Mast. Surg. Edin., L.S.A. Lond., to Rhoda Maud, youngest daughter of C. H. Tonking, Esq., Roskear Villas, Camborne.

RITCHIE—SOUTTAR.—On July 12th, at Beaconsfield-place, Aberdeen, James Ritchie, M.A., M.D. Edin., Oxford, to Lily, daughter of James Souttar, F.R.I.B.A., Aberdeen.

TENCH—STANLEY.—On July 16th, at Christ Church, Lancaster-gate, Sidney E. Tench, M.R.C.S., L.R.C.P., of Brixton, to Mabel, youngest daughter of the late Charles Stanley, of Lancaster-gate, W.

DEATHS.

BOWMAN.—At Charlmont-place, Armagh, Robert Bowman, Surgeon-Colonel I.M.S.

FARR.—On July 16th, at Strathallan, Owls-road, Boscombe, Septimus Briggs Farr, M.R.C.S., L.R.C.P. Edin., L.S.A. Lond., aged 65 years.

FOX.—On July 20th, at Mount Park-road, Ealing, W., Oscar Harger-Fox, M.R.C.S., in his 84th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

BRITISH MEDICAL ASSOCIATION MEETING AT EDINBURGH.

DURING the forthcoming meeting of the British Medical Association at Edinburgh the Representatives of THE LANCET can be consulted at the Imperial Hotel with regard to our report of papers and proceedings.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

INCARCERATION OF THE PENIS.

DR. THEODOR FLORAS, principal medical officer of the Anatolian Railway, Constantinople, reports a case of incarceration of the penis in the *Deutsche Medicinische Wochenschrift* of July 14th. The patient was a railway employé, about fifty-five years of age, who, presumably while in a state of intoxication, in presence of a companion passed his relaxed penis through the aperture of an iron screw-nut, this aperture having a width of only 1½ centimetre (0·6 in.). The matter was treated as a joke, and encouraged by his companion he forced the nut with a twisting movement until it arrived at the attachment of the ligamentum suspensorium urethræ. He was subsequently unable to remove the nut, but nevertheless went to work that same day and also the next. On the evening of this second day he consulted a surgeon who drew off his retained urine with a fine catheter, prescribed a diuretic, and directed lead lotion to be applied to the penis. It was only next morning that Dr. Floras saw him, more than thirty-six hours after the application of the nut. The man was then in a state of the greatest alarm and uneasiness, his penis hung down like an enormous tightly filled sausage, and the diffuse swelling was so great that it was difficult to find the nut among the infiltrated tissues. Amputation seemed to be unavoidable, but before resorting to it the man was taken to the engineering shop and held by two men in the upright position against a large anvil. The penis, with the square nut encircling it, was then held horizontally on the anvil, a slight cut was made in the nut by a sharp chisel struck by a hammer, and this cut was cautiously deepened until an iron wedge could be driven into it, whereupon the nut broke in two. The internal screw threads of the nut had sunk into the tissues of the urethra and had caused ulcerative and necrotic changes, but in a few days all these symptoms disappeared and the man returned to his work. Dr. Floras refers to a somewhat similar case recorded by M. Ameisen, quoted in the *Centralblatt für Chirurgie* for 1897, p. 1166.

ANTI-VIVISECTION TACTICS.

A MEDICAL man at Clifton, and perhaps many medical men in the neighbourhood, have received the following document:—

BRISTOL AND WEST OF ENGLAND ANTI-VIVISECTION SOCIETY.

20, Triangle, Bristol, July, 1898

SIR,—As we are often asked if we can give the name of a doctor who is opposed to vivisection we should be glad to keep a list of such for the convenience of inquirers.

Will you therefore kindly answer the enclosed question and return this paper to the above address?

I am, yours faithfully,
F. I. BAKER, Secretary.

QUESTION:—

Are you opposed to Vivisection?

It is to be hoped that all medical men, whether sympathising or no with the anti-vivisection movement, will leave this circular unanswered. To attempt to obtain patients from brother practitioners through the medium of Mr. F. I. Baker would be in opposition to all right ideas and the stress of competition would never excuse such behaviour.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 2nd, in the Appointments column, an error has crept in which I would like corrected, as already a good deal of misunderstanding and inconvenience has been caused me thereby. It is there stated that H. W. Cooper, M.D. Balt., U.S.A., has been appointed resident medical officer and vaccinator at the Carcoar Hospital, New South Wales. No such appointment has been made. W. H. Cooper, M.D. Balt., U.S.A., succeeded me as medical officer to the Galley Mont Gold Mining Company, Galley Swamp, a position I held as visiting medical officer until it was decided to have a medical man resident on the "field," when my appointment lapsed. Hence, I presume, the error.—I am, Sirs, yours faithfully,

A. W. HAWTHORNE, M.D. R.U.I.,
Resident Surgeon Carcoar District Hospital; Government Medical Officer and Vaccinator, Carcoar District.

Carcoar, N.S. Wales, June 11th, 1898.

THE HEAT IN NEW YORK CITY.

A CORRESPONDENT writes: "New York has just experienced a heat wave of exceptional intensity. The hot weather came in with July. On the 1st of the month the thermometers in different parts of the city registered at four in the afternoon from 90° to 97° F., accompanied with much humidity. This temperature, however, was far exceeded on Sunday, July 3rd, on which date occurred the hottest day for many years—in fact, it is said that not since 1881 has the mercury risen to such a height. The peculiar feature of this excessive degree of heat was the comparative absence of humidity—only 70°—and the presence of a breeze from the south-west travelling at the rate of fourteen miles per hour. Ordinarily a breeze from this quarter tends to mitigate the most severe temperature, but on this occasion it exerted a contrary effect and served to bring upon the city such an excess of heat as will be remembered for many a long day. The current of air had many of the characteristics of a simoon and struck

Digitized by Google

one like the blast from a fiery furnace. According to the reports from the weather bureau the highest temperature of the day was 99° in the shade, but it must be understood that the office of the bureau is several hundreds of feet above the ground and many thermometers in the streets registered over 100°, while some on Broadway in the sun stood at from 105° to 115° between the hours of 12 P.M. and 4 P.M. The worst of it was there was no relief. Although indoors the air was stifling, it was even more unpleasant outside The harder the wind blew the hotter it was. The penny boats and pleasure steamers, the usual resorts of New Yorkers in the torrid season, were swept by the burning wind. It is needless to say that there were many cases of heat prostration. The condition of the poor inhabitants of the east side streets was especially pitiable. Few towns in the world possess so overcrowded a district as the section inhabited by the poor of New York. In this part of the town the slum dwellers are herded together in huge tenement buildings crowded in small box-like rooms. The streets are narrow and often paved with asphalt, which attracts and conserves the heat as no other description of pavement does, and as a result the distress and mortality reached a point seldom known. The fall in temperature was very gradual up to eight o'clock, then the earth commenced to cool, until at eleven o'clock the thermometers in the street stood at 89°."

A SHORT WAY WITH AN UNREGISTERED CLUB DOCTOR.

THE Barmen clubs having quarrelled with their medical men these have resigned and strangers have been imported into the town to take their posts—amongst them a Swiss lady, who, though an M.D. of Zürich, has not a German qualification, has been placed in charge of the female members of the clubs. This coming to the knowledge of the local authorities they immediately caused a notice to be served on the committee of the club informing it that every member would be liable to a penalty of 10s. for every day that the unqualified lady practised.

"UNFORTUNATE PUBLICITY."

To the Editors of THE LANCET.

SIRS,—As in THE LANCET of the 16th inst. you have instructed me to withdraw an advertisement which you reproduced in full you will no doubt, in fairness to me, state your grounds for so doing and print this letter in your next issue. I am entitled to assume that, as competent editors, you made yourselves acquainted with all the facts of this particular case before remarking upon it and therefore I need not at present allude to them. I shall be glad to know the precise grounds upon which you object to this advertisement and as I like, when possible, to understand the reasons for adopting any line of conduct I should be obliged if you would kindly enter into some detail and point out what evils you fear and in what manner you expect them to arise. I should also be glad to learn whence you derive the authority to address me in such dictatorial terms. I am, Sirs, your obedient servant,

Southampton, July 19th, 1898. JOHN BULLAR.

*** We have not instructed Dr. Bullar to do anything. We have recommended him to withdraw his advertisement which, by the way, was not reproduced in full. The objections to such advertisements are patent; they advertise the writer of the book in his medical character to a lay public. We fail to see in what way our recommendation was a dictatorial one and at the risk of further offending Dr. Bullar we beg to repeat it.—ED. L.

THE LATE MR. ARTHUR JEFFARES BARLOW: AN APPEAL.

IT will be remembered that an appeal was made in THE LANCET of May 14th on behalf of the widow of the late Mr. Arthur Jeffares Barlow. As the sum received is up to now only small we again give the names and addresses of those to whom subscriptions may be sent:—Dr. J. W. Moore, 40, Fitzwilliam-square West, Dublin; Dr. John Barton, 26, Upper Merrion-street, Dublin; Dr. C. J. Clibborn, 76, Owen-terrace, University-street, Belfast; Dr. L. H. Ormsby, 92, Merrion-square West, Dublin; Dr. Henry, 2, Lewisham-park, Lewisham, London, S.E.; and Dr. A. Matson, 619, Holloway-road, London, N., who desires to acknowledge a subscription of £2 2s. from Sir Edwin Saunders.

MR. MOULD FAILS TO FIND MR JOBLING.

To the Editors of THE LANCET.

SIRS,—I was interviewed to-day by a man who told me he had just come to the neighbourhood to begin business and was desirous of obtaining my patronage. I asked him what business he was in and he replied that he was an undertaker. I rose to show him out when he remarked, "Of course, doctor, *as is usual*, I am prepared to offer you a commission." He left immediately. Is the game really played as low down as this? I am, Sirs, yours faithfully,

July 18th, 1898. F. C.

A Twenty-five Years' Subscriber will find several articles on the appointment of medical referees in the columns of THE LANCET during the past six months. The appointments are in the hands of the Home Secretary and application for them should be addressed to that Minister and sent under cover to the "Private Secretary to the Secretary of State, Home Office" (see THE LANCET, April 23rd, 1898, p. 1137). As was stated last week, the list of medical referees for certain county court circuits is now complete (see THE LANCET, July 16th, 1898, p. 168)

Assistant.—We know no other method of hearing of such posts save advertisement. Applications for colonial service should be made to the Colonial Office, Downing-street, S.W.

Pes.—The "Toe-Post" Shoes are made by Messrs. Holden Bros., 223½, Regent-street, W. Any surgical bootmaker will make sandals to order.

F.R.C.S. (Southsea).—The Jacksonian Prize on Tetanus has not been published. The essay is in the Royal College of Surgeons of England.

Medical Diary for the ensuing Week.

CERTIFICATE.

At the request of the Apenta Company of Budapest, I hereby certify to them that I have for a considerable time repeatedly examined the **APENTA SPRINGS** at Ofen (Budapest) and the filling of the water, which were placed under my scientific supervision, and that I have become convinced that the working is conducted very satisfactorily from a hygienic point of view.

I have also satisfied myself by repeated personal investigations that the **APENTA WATER** as despatched is constant in its chemical composition.

HARVEY'S
SUGAR-FREE PALE ALE

(Protected by Her Majesty's Royal Letters Patent).

The only **ALE** which may be drunk with impunity by persons with whom, from various causes, ordinary Beer does not agree.

ABSOLUTELY FREE FROM SUGAR.

Mr. T. FAIRLEY, Leeds City and County Analyst, F.R.S.Edin., F.C.S., F.I.C., certifies, June 3rd, 1896, that this Pale Ale is

"ABSOLUTELY FREE FROM FERMENTABLE SUGAR."

For further analyses see THE LANCET, May 22nd, 1897, and the BRITISH MEDICAL JOURNAL, April 24th, 1897.

An article in THE LANCET says: "For years I have been unable to take beer as a beverage on account of the lethargy, indigestion, pain, and stiffness which invariably followed such indulgence; but for three months continuously I have taken one glass of this Sugar-free Pale Ale at luncheon without the slightest 'rheumatic' effects."

SOMATOSE

is an Albumose Food product. It is prepared from meat, and contains the albuminous elements of the latter in an easily soluble form. The salts present in SOMATOSE correspond to the nutritive salts of fresh meat, among which occur Phosphate of Potassium, so important in the formation of muscular and cellular tissue.

SOMATOSE is a Tasteless, Odourless Powder,—is easily tolerated, even by the most delicate stomachs. It is invaluable in Wasting Diseases, in Convalescence from Exhausting Diseases, and is especially indicated in cases of Children of Backward Development.

SOMATOSE is well borne when no other aliment can be administered. It is also of the greatest service in cases requiring rectal alimentation.

SOMATOSE has been found invaluable in the uncontrollable vomiting of pregnant women and in vomiting following the administration of chloroform.

SOMATOSE is indicated in all conditions where an invigorating and easily absorbed food is required. With the aid of SOMATOSE it is possible to tide the patient over critical periods, since it is capable of acting for a long time as a complete substitute for other nitrogenous foods.

ADULT DOSE: One teaspoonful three times a day, in milk, soup, coffee, cocoa, &c.

The following is the Analysis of SOMATOSE as obtained by Goldman:—

Water	9·20
Total Nitrogen	12·84
Albumoses	77·85
Peptone	2·20
Ash	6·78

IRON-SOMATOSE

(Ferro-Somatose).—An excellent tonic, containing the albuminous substances of the meat (albumoses) organically combined with Iron in the proportion of 2 per cent. of the latter. Under the use of Iron Somatose the weight of the body is increased and the amount of hæmoglobin is augmented. Iron Somatose combines in a most suitable way the well-known and appreciated properties of Somatose with a good Iron preparation.

SPECIAL INDICATIONS: Chlorosis and Anæmia. DAILY DOSE: 75 to 150 grains.

MILK-SOMATOSE

(Lacto-Somatose).—A strength-giving food containing the albuminous matter (albumoses) of the Milk, with 5 per cent. of Tannic Acid in chemical combination. The chief indications for Milk-Somatose are the various chronic maladies of the digestive organs, and especially those disturbances of digestion which, as in Enteroptosis and Anæmia, can be referred to the atonic condition of the muscular organs of the stomach. Milk-Somatose is a good flesh-forming preparation, without irritation, and slightly astringent with patients of weak or diseased digestive organs. In the case of Typhus maladies it is of great value.

Samples and Literature can be had on application to the Wholesale Depôt for all Bayer's Drug Specialities:—

BAYER'S
PHARMACEUTICAL SPECIALITIES

TRIONAL. *(Diethylsulfonmethylethylmethan).*—A most reliable and quickly acting hypnotic of the Sulphonal group. In simple insomnia Trional will produce sleep with absolute certainty in from fifteen to thirty minutes. Has no influence on the heart, respiration, or temperature.

DOSE: From 15 to 30 grains. Best administered in a cupful of hot liquid, or in aerated water, when a considerably smaller dose suffices.

TANNIGEN. *(Acetyl of Tannin.)*—A most valuable remedy in cases of Acute and Chronic Diarrhœa, and invaluable for the Summer Diarrhœa of Children. Tasteless and Odourless. Passes through the stomach entirely unchanged, decomposition only occurring in the intestines.

DOSE FOR CHILDREN: 2 to 5 grains.
DOSE FOR ADULTS: 8 grains every three hours.

TANNOPINE. *(Hexamethylene-tetramin Tannin).*—A New Intestinal Astringent. Has an excellent effect, without secondary phenomena, in all the various kinds of Enteritis. Has given especially good results in cases of Tuberculous Inflammation of the Bowels, in cases of Non-Tuberculous Subacute and Chronic Intestinal Inflammation, and also in cases of Typhoid.

DOSE FOR CHILDREN: 3 to 10 grains.
DOSE FOR ADULTS: 16 grains, two to four times daily.

SALOPHEN. *(Acetyl-paro-amydosalol).*—The best substitute for Salicylate of Sodium, as it acts quite as promptly, but without any of the unpleasant after-effects of the latter. Its special indication is Acute Articular Rheumatism. It is invaluable for Influenza, Migraine, &c.

DOSE: 16 to 24 grains three or four times a day.

LYCETOL. *(Tartrate of Di-Methyl-Piperazine).*—Combines the Uric Acid solvent properties of Piperazine, with the diuretic properties of Tartaric Acid. Invaluable in all cases of the Uric Acid Diathesis.

DOSE: 16 to 32 grains daily. Best administered in aerated waters, such as Seltzer, &c., or in granular effervescing form. (Effervescing Lycetol: Messrs. A. Bishop & Sons, Ltd.)

IODOTHYRINE. The active principle of the Thyroid Gland. A stable product containing a definite amount of the Iodine compound which forms the active principle of the Gland. Iodothyrine acts more quickly than either the fresh or dried gland substance. It is a preparation of perfectly definite composition, stable and permanent.

ADULT DOSE: 5 grains two to eight times a day.

EUROPHEN. *(Isobutylorthocresoliodide.)*—A perfect substitute for Iodoform. Odourless and non-toxic. Has a specific gravity five times less than that of Iodoform. Non-irritating and does not produce a rash. Adheres closely to mucous surfaces. Specially indicated in Syphilitic Diseases, Gynæcology, Burns and Bedsores, Eye, Ear, Throat, and Nose Affections, &c., &c.

ARISTOL. An Iodine Derivative containing 48% of Iodine. Is an ideal Cicatrisant, forming an absolutely unirritating covering over the surfaces on which it is placed, under which the processes of granulation and cicatrization proceed with extraordinary rapidity. It is a convenient, Non-Irritating and Effective Antiseptic Dressing in General Surgery, Dentistry, Gynæcology, Diseases of Eye, Ear, and Nose. In the treatment of Burns Aristol has proved to be of the greatest value, its antiseptic and healing properties being specially marked.

PROTARGOL. A new silver preparation for the treatment of Gonorrhœa, containing 8% of silver, easily soluble in warm or cold water. Has a better penetrating effect on the tissues than any other known silver preparation. Non-irritating. Usual strength of solution, ¼ to 2%. An excellent antiseptic in the treatment of Wounds. Of the greatest possible service in Ocular Therapeutics.

PHENACETINE-BAYER, SULPHONAL-BAYER, PIPERAZINE-BAYER, SALOL-BAYER, SOMATOSE, IRON SOMATOSE, MILK SOMATOSE, ANALGEN, LOSOPHAN, TETRONAL, &c.

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic,** we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialties—

ELBERFELD FARBEN FABRIKEN CO., Ld., 19, St. Dunstan's Hill, LONDON, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

JMR **LACTOPEPTINE in Powder and Tablets (5 gr.).**

JMR **LACTOPEPTINE in Powder and Tablets (5 gr.).**

LACTOPEPTINE For Diseases of the Stomach.

Indications: Dyspepsia, Indigestion, Vomiting in Pregnancy, and all diseases arising from imperfect nutrition, such as Anæmia and Cholera Infantum.

Dose: 10-15 grs.

Marketed: In powder and tablets (5 gr.) 1 oz. 3/-, 4 oz. 10/6, 8 oz. 20/6; prices for dispensing and to the Medical Profession only.

Analyses by Prof. Bartlett, Prof. Attfield, and Dr. Jeserich

JOHN MORGAN RICHARDS, 46, Holborn Viaduct, London.

Address in Medicine

ON

MEDICAL PROGRESS IN THE PAST QUARTER OF A CENTURY.

Delivered at the Annual Meeting of the British Medical Association at Edinburgh, July, 1898,

BY THOMAS RICHARD FRASER, M.D., F.R.C.P. EDIN., LL.D. ABERD., F.R.S.,

PROFESSOR OF MATERIA MEDICA AND CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH.

MR. PRESIDENT AND GENTLEMEN,—When this Association last met in Edinburgh the Address in Medicine was delivered by the accomplished and universally beloved physician, Dr. Warburton Begbie, and notwithstanding the lapse of time I can still recall—and there are others here also able to recall—the thesis which formed the subject of the address, expressed in the inquiry, Has the practice of medicine made a single step since the time of Hippocrates? In dealing with this thesis Dr. Begbie described the history of medicine from its beginnings, as only could be done by one who had not only carefully studied the writings of the fathers of medicine, but had also made himself familiar with the work of their successors. The doctrines regarding the nature of disease, which successively replaced each other during the twenty-three centuries dealt with, were clearly described, and, as was to be expected from the practical physician, he fully discussed the bearings of these doctrines upon treatment and pointed to the more conspicuous acquisitions in the healing art which had enriched practical medicine. He had the opportunity of showing how greatly medical doctrine had been transformed by Harvey's discovery of the circulation of the blood; how the diagnosis of pulmonary and cardiac disease had received an extension and previously unknown definition, from Laennec's discovery of auscultation; how the memorable discoveries and courageous applications of nitrous oxide, ether, and chloroform by Horace Wells, Morton, and Simpson had deprived the knife of the surgeon and the reproduction of animal life of much of their former terrors and anxieties; and how by that vaccination, which will ever be associated with the name of Jenner—the first and still unsurpassed means of restricting the ravages of a fatal infectious disease—an almost incalculable benefit had been conferred upon the human race. From his elaborate survey of the history of medicine he concluded that no general doctrine—chemical, physical, humoral, or physiological—had been propounded which satisfactorily explained the nature and production of disease; that therapeutic advancement had been obtained, chiefly by the observation of patients, by adhesion to the classic method of rational empiricism; and that by this method such valuable accessions to the means of treating disease had been gained as the administration of turpentine in pulmonary gangrene and bronchitic affections; of quinine in intermittent fever; of iodide of potassium in syphilitic periostitis and thoracic aneurysm; of bromide of potassium in epilepsy; and of cod-liver oil in pulmonary tubercle.

It may not be without interest to consider to-day how far, and in what directions, this great and wide subject of medicine has chiefly advanced since Dr. Begbie delivered his address. The intervening period is the relatively brief one of scarcely a quarter of a century. It has, however, been signalised by a great increase of knowledge regarding the fundamental sciences of chemistry, physiology, and morbid anatomy; by the creation of pharmacology as a science of the action of remedies; by steady advance in symptomatology and diagnosis; and, above all, by so remarkable a development in our conceptions of the nature and production of many diseases that we appear almost to have attained a position vainly sought for during centuries by our predecessors of being able to formulate a doctrine of disease founded upon the satisfactory basis of experimental demonstration, and sufficient to explain many of its forms and to already provide us with assured means and principles for its prevention and treatment. While fully acknowledging the merits of the workers in medical science and practice by whom this gratifying progress has been made it cannot be forgotten that the necessary pioneer work was undertaken amid difficulties of exploration in dark and unknown regions, and that but for this pioneer work the present generation would not have been able to reap so prolific a harvest of medical discovery. This indebtedness to our predecessors is nowhere more conspicuously shown than in the advancements that have been made in the diagnosis of disease. Observation, careful and intelligent, practised by the fathers of medicine had already constructed a nosology sufficient to distinguish the great majority of diseases, and so complete that it is doubtful if much advance could have been made if the methods in use at the commencement of this quarter of a century had alone been trusted to. The introduction, however, of physical aids to our senses and of chemical applications and methods—each rendered possible by the growth of collateral science—has placed us in a position from which we have been able to advance in accuracy of diagnosis and even in the discovery of new diseases.

MODERN ADVANCE IN ACCURACY OF DIAGNOSIS.

By the apparatus now in use for blood determinations the condition of this fluid in regard to many of its most important constituents can be exactly determined and information can be obtained valuable for treatment and previously unattainable by any perfection of intelligent observation by means of the unaided senses. The sphygmograph depicts with precision of detail changes in the pulse which are difficult to apprehend by the unaided finger even after a long apprenticeship and, above all, increases the usefulness of the physician by indicating the characters which without its use he should be trained to detect. He is thus enabled to appreciate changes which are not only of the highest value in prognosis, but are also frequently sufficient either in themselves or aided by the most superficial of further observation to justify without auscultation the diagnosis of the cardiac lesion which is present. The ophthalmoscope has increased the certainty of diagnosis of many nervous affections and toxic processes and some of the difficulties of clinical observation have been overcome by radiography, whose capabilities, however, are as yet undeveloped. By the introduction of chemical processes applied especially to the examination of the stomach contents and of the urinary and other secretions, diagnosis has also been advanced and previously unknown precision has been obtained. The agglutinated effects of the blood-serum in certain infective diseases, as typhoid, Malta and relapsing fevers, and in cholera and anthrax, upon their respective pathogenic organisms, and the application of chemical pigments to reveal the existence of the microscopically minute organisms of such diseases as pulmonary tubercle, pneumonia, and diphtheria, has removed many of the perplexities of diagnosis and rendered identification almost a mechanical art.

While by these and other means the diagnosis of diseases—a fundamental work in the art of medicine—has conspicuously advanced during the last quarter of a century, this advancement, however great, does not in itself justify any claim to a nearer approach to the realisation of the highest aims and objects of medicine. Diagnosis, for the most part, deals only with symptoms, it has no immediate concern with the true nature or course of the disease, and until this has been determined progress in treatment can only be tardy and unsatisfactory. The history of medicine has shown that the advance in these two departments has rarely, if ever, been parallel or equal. The one may reach a position of almost ideal perfection, while the other still remains in the initial stage of vague speculation. This is exemplified by the present state of knowledge of nervous diseases. Minute symptoms have been identified and have been so arranged in groups as to constitute special diseases, and thus numerous forms of disease associated with morbid lesions of parts of the spinal cord or brain have been created. The elaboration is a remarkable triumph of painstaking and skilful observation in symptomatology and in morbid anatomy. It presents a field for the training of the powers of observation and reason probably unsurpassed by any other problems in practical medicine, and the solution of these problems is undoubtedly a cause of satisfaction to the physician, as it frequently also is to the patient. To what extent, however, is the patient a gainer; to what extent is the object of diagnosis and of all medical knowledge fulfilled? It

Digitized by Google

must be admitted that the gain in most cases is disappointing. The natural course of the disease is no doubt often beneficially modified, but usually to only a slight extent, unless surgical treatment is successfully applied, which even the scientific discoveries of Ferrier and Horsley and the surgical skill of Durante, Kocher, Macewen, and others have rendered possible in relatively few cases. Whether the investigation of the condition of the patient leads to the diagnosis of acute ascending paralysis or anterior cornual degeneration, of spastic paraplegia or locomotor ataxia, of syringomyelia or bulbar paralysis, the methods of treatment are much the same; and while we may have some satisfaction in adopting measures to relieve symptoms or to protect the patient against conditions favourable to the progress of the disease, or to increase the general powers of resistance, we most frequently find ourselves in the mortifying position of being unable to cure the disease. In those cases, on the other hand, where it is possible to advance from diagnosis to the determination of the actual cause of the disease, when remedies are employed which have been proved to be curative as regards that cause, the disease, whatever be its position in the artificial nosology of nerve affections, may in many instances be arrested in its progress and may even be cured provided the affected tissues have not already undergone incurable destruction.

At the present epoch in medicine it is especially interesting to recognise that the latter gratifying results are to be obtained when there is reason to believe that the disease has been caused by a toxic substance present in the body and that according as this substance be the poison of syphilis, or of rheumatism, or of malaria is the cure effected by remedies which have been proved capable of annulling the toxic effects of these poisons. It is thereby shown that the disease is not truly a product of the structural alterations which are present, but of a hurtful substance or poison capable among other effects of producing these structural alterations. Similar facts are observed with many ordinary poisons and an association, highly significant in regard to the production of disease, is thus indicated. Many of the more common poisons produce changes in structure closely simulating the changes of disease, as the peripheral neuritis, anterior cornual degeneration, granulo-fatty degenerations, and arterial sclerosis of lead, the liver steatosis and yellow atrophy of phosphorus, and the fatty degenerations and diffuse sclerotic hyperplasia of the liver, the peripheral neuritis and the atheromatous changes in blood-vessels produced by alcohol. By such facts, acquisitions of modern pathology, it is strongly suggested that the structural changes found in many diseases may, after all, be mere manifestations, associated with other effects, of a cause which would thus assume the importance of being the essence, the *vera causa*, of the disease, and that this essence is a toxic substance. This idea is rapidly becoming the predominant doctrine of the present-day conception of disease and as investigation proceeds it is almost daily receiving support from new facts. It has been demonstrated that the body is constantly subjected to the risks of poisons produced within itself, as well as of poisons introduced into it from without. Many of the poisons produced in the body, such as the ptomaines and leucomaines, are of the chemical nature of the previously known alkaloids, and not a few of them rival the vegetable alkaloids in toxic power and reproduce their leading effects. Nervine, for instance, is lethal in minute doses and acts in many respects like pilocarpin; while muscarin finds its analogue in the active principle elaborated by poisonous fungi. The organism even in a state of health is a veritable storehouse of these toxic substances. Many of its normal constituents, such as potash salts and carbonic acid, are well-recognised poisons; many of the products of its glands, such as saliva and bile, contain toxic ingredients; many of the substances which are formed in the processes of disassimilation, and which enter such secretions as the urine and the intestinal canal, are capable of disordering health and even of endangering life; and in disorders of function, even if they amount to little more than mere disturbance of nutrition, poisons not found in the healthy body are generated and produce the symptoms of disease. By such toxic influences the symptoms of cholæmia, gout, rheumatism, uræmia, diabetic coma, stercorræmia, and probably also of chorea, sunstroke, neurasthenia, asthma, and the idiopathic anæmias receive a sufficient explanation, even although the toxic substances have not in all cases been identified. The doctrine of the toxic origin of disease has also been applied to mental affections. Auto-intoxication from poisons produced in the intestinal canal is believed to be an important factor in the causation of insanity and already neurologists, such as Nissl and Van Giesen, have expressed the opinion that the toxæmic theory is destined to clear away much of the present vagueness regarding the pathogenesis of mental disease. Further, it is not improbable that in cancer auto-intoxication by a poison generated in the cancer cells, equally with and in some instances to a greater extent than structural degenerations of invaded tissues, accounts for the symptoms and for the fatal termination—a probability which has been strengthened by the separation from cancer of a substance possessing a hyperthermic and powerfully lethal action.

TOXIC ORIGIN OF INFECTIOUS DISEASES.

The widely acting pathogenic influence of poisonous substances has, however, received its most definite and convincing support from the remarkable discoveries in bacteriology which have signalised this period. The gravity and wide prevalence of infective diseases had rendered them a subject of special study from the earliest period. Rhazes in the seventeenth century propounded the view that small-pox was essentially a fermentative disease and thus originated the doctrine of the fermentative nature of all infectious disease. Previously to this time a theory of the parasitic origin of these diseases had been propounded and its more enthusiastic supporters gave a reality to their views by such statements as that syphilis was caused by a minute worm, and measles, small-pox, and plague by infusorial animals or invisibly minute insects. With the introduction of the compound microscope the parasitic theory disappeared in this gross form of it and the fermentative theory was again adopted. It was not, however, until 1861, when Pasteur's great discovery of the nature of butyric fermentation was made public, that the sufficiency of the theory became revealed. His demonstration of the essential part played by minute-living structures in the transformations which constitute the process of fermentation at length removed the process from the mysteries which had previously surrounded it, and opened up applications to the pathogenesis of infective diseases which have revolutionised medicine. He pointed out that the organisms of fermentation are similar to those which had already been discovered by Rayer and Davaine in anthrax. He subsequently demonstrated the virulent nature of the microbes of pyæmia and infectious gangrene, and following Koch's work on the cultivation outside of the body of the bacillus of anthrax he proved also that this bacillus, as well as that of cholera de poules, is able when grown in suitable media to reproduce itself almost indefinitely and to retain for many generations its power to cause the symptoms of the original disease when inoculated into animals. The way was thus opened up for important additions to the knowledge of the etiology of infective diseases, and in rapid succession the pathogenic micro-organisms of swine fever, morve, tubercle, Asiatic cholera, septicæmia, erysipelas, pneumonia, and numerous other infective diseases were discovered. The pathogenic action of the microbes was at first attributed either to mechanical obstruction of the blood-vessels, caused by their accumulation in them which resulted in asphyxia of organs essential to life; or to a biological action which enabled them to appropriate nutritive materials destined for the tissues of the body and thus to deprive these tissues of life. While in the case of a few of them both of these actions may to a slight extent explain their effects, it was subsequently proved that these effects are mainly caused by the poisons which they produce. The poisons are of complex composition; some are alkaloids and others modified proteids, and others, again, have altogether unknown chemical composition. Many of them are of extreme and almost indefinitely great activity; one milligramme, for instance, of the dry poisonous constituents of tetanus toxin is sufficient to kill a horse, or 600 million times its weight of living tissue; while the hypothermal effects of tubercle toxin are appreciable when the dry toxin, in doses of from one to two-tenths of a milligramme, is injected, representing a strong reaction on 60 millions of its weight of living human substance. Like other poisons, they also are capable of producing structural changes, exemplified in the skin eruptions produced by many infectious diseases; in the focal necrosis of peripheral nerves produced by the diphtheria poison; the fatty changes and longitudinal fibrillation of the heart muscle produced by this poison and also by that of

Digitized by Google

anthrax; the cerebro-spinal meningitis produced by the poison of influenza; the anterior cornual and muscle degenerations and the neuritis produced by the poisons of tetanus and diphtheria; the acute parenchymatous and hæmorrhagic nephritis produced by serpents' venom; and in the production of nodules in the lungs, reproducing the characteristics of pulmonary tuberculosis, by dead tubercle bacilli.

The demonstration of the toxic origin of infectious diseases has thus added greatly to the number of diseases which are caused by poisons and has thereby been largely instrumental in establishing the doctrine of the toxin origin of disease. Unlike the older doctrines of the iatro-chemists, humoralists, and physiologists, this doctrine is supported by an abundance of convincing facts; and it may confidently be anticipated that it will have an endurance which former systems of medicine have not possessed. Large numbers of disease-producing poisons are thus ever present in the body, created by the normal processes of life and abundantly produced by departures, even in themselves unimportant, from these processes. Many substances well known to have poisonous properties are intentionally introduced into the body, such as alcohol, tobacco, tea, and opium, while others, such as lead, accidentally find their way into it. The respiratory passages and intestinal canal are crowded with micro-organisms and they teem in the soil, air, and articles of food. Many of them are producers of virulent poisons and when they effect a lodgment in the body and find conditions congenial to development they proliferate with so great rapidity that a single bacterium may in twenty-four hours have multiplied itself into many millions of separate toxin-creating organisms. In these circumstances it is of interest to inquire what defence man and other animals can oppose to the disease and death-producing poisons by which they are so constantly endangered. Instances have long been known of a possession of defensive powers against the ordinary poisons, organic or inorganic. Certain animals are by hereditary endowment able to receive with impunity large quantities of poisons, which in minute quantities are hurtful to other animals, well exemplified in the enormous quantities of belladonna and opium which may be administered without injury to herbivora. It is also notorious that man and other animals may become so habituated to the action of several toxic substances that in the course of time doses greatly in excess of the minimum lethal are no longer able to cause death or even much inconvenience. Such acquired powers of defence are produced against arsenic, opium, alcohol, and tobacco, and they are also illustrated in the effects of nitrile ethers. Explanations for these exceptional powers of defence have been found in the special activity of the processes of elimination and particularly of elimination by the kidneys, whereby the quantity of poison requisite to cause injury is prevented from being present in the blood; in an unusual power of producing decomposition, probably dependent on special chemical conditions of the blood; and on the property which certain organs possess of absorbing and retaining toxic substances and of thus preventing their access to the structures on which they act, in quantity sufficient to be hurtful. In the case, further, of many organic poisons, absorption and diffusion are impeded by the walls of cells, as in the instance of the slow absorption of strychnine through the stomach walls and of many albuminoid poisons though the intestinal epidermis. These explanations, however, do not account for all the observed phenomena, and it must in the meantime be assumed that tissues may gradually become accustomed, possibly by exhaustion, to the perturbations produced by substances which modify this normal condition, so that by-and-by a tolerance is induced. Anticipating some statements which will afterwards be made, a fundamental difference exists between both congenital and acquired defence against ordinary poisons and that resulting from the action of disease toxins, venoms and such-like poisons, in so far that in the former there is not produced in the blood any substance which plays the part of a counter-poison or antitoxin. The subject has, however, gained a new importance from the remarkable facts discovered in connexion with the poisons generated by pathogenic micro-organisms and in connexion also with other poisons of very similar chemical composition, represented especially by the venom of serpents and by the vegetable products abrin and ricin.

THE PRODUCTION OF ARTIFICIAL RESISTANCE TO DISEASE.

It had long been known that many infectious diseases conferred upon those who had suffered from them a power of resistance against subsequent attacks of the same disease. After the discovery had been made—and to this I have already alluded—of the microbian origin of infective diseases, it was experimentally shown that if the microbes constituting the cause of any infective disease were inoculated into animals, not only were symptoms of the disease produced, but also that the animal, if it survived, reproduced still further the events of an infectious illness by acquiring a power of successfully resisting the morbific influence of the same microbes subsequently inoculated. It has likewise been found that each of these events could be reproduced by the filtered and therefore microbian-free solution in which the pathogenic microbes had been cultivated, and thus it was demonstrated that neither the original disease nor the subsequently acquired production was actually due to the microbe, but to toxic substances produced by it. From this position the further great advance was made that the blood-serum of protected animals, itself destitute of poisonous properties, when introduced into non-protected animals, conferred upon them a resisting power which might be so great that even large lethal doses of the virulent micro-organism and of its toxin no longer produced death or even symptoms of poisoning. These remarkable results of experiment deservedly claim much attention. They irrefutably demonstrate that infectious diseases are in their essence poisonings; they throw much light on the mystery, previously shrouded in metaphysical phrases, of the nature of the protection acquired by attacks of infectious disease or conferred by vaccination; and they have not only at once led to valuable therapeutic results, but they indicate further applications both in the prevention and treatment of disease, exceeding in their possibilities any expectations that had previously been originated by discovery in medical science. Inquiry into the nature and cause of this protection has thereby been removed from the position of speculation long occupied by it to one in which experimental methods could be pursued with some hope of solving the problems. Many of the results, however, are yet difficult to explain, and considering that new facts bearing upon them are almost daily being obtained it is not to be expected that altogether satisfactory solutions have been found or unanimity of opinion been obtained. More especially does this apply to the nature of the process whereby protection or immunisation is obtained, to the origin of the protection producing substances or antitoxins, and to the manner in which they act as curative or therapeutic agents.

As in the case of some of the ordinary poisons, mineral and vegetable, it may be admitted that a portion of the acquired protection is due to the tolerance brought about by the accustoming of the structures of the body to the action of the poison, but this tolerance could not continue for the long periods during which acquired immunity sometimes persists after the infected disease has been recovered from. It may also be admitted that pathogenic micro-organisms absorb and thus remove from the body certain constituents necessary for their growth and vitality whose removal may, to some slight extent, render the body unsuited for the further growth of these organisms; but, apart from other objections that might be advanced, it is inconceivable that this cause could operate in the bodies of animals which so rapidly change the composition of all their constituent parts and that, therefore, the substances which have been removed would not very soon be again restored to the body and thus render it vulnerable to fresh infections. The doctrine of phagocytosis, enunciated and ably and strenuously supported by Metchnikoff, in which protection is attributed to the power possessed by leucocytes of absorbing and destroying microbes, may, to a limited extent, account for the destruction of living microbes, but it probably accounts to a greater extent for their disappearance after life is extinct; while it can have but little influence upon the soluble toxins which, since the introduction of the theory of phagocytosis, have been proved to be in most cases the true cause of the disease symptom. The frequent persistency of immunity not only exemplified in the after-history of patients who have recovered from certain of the infectious diseases, but also in vaccination against small-pox, while it alone serves to disprove each explanation as yet advanced of the essential nature of acquired protection, must be taken into account in formulating explanations. The micro-organism of an infected disease introduced into the body produces the characteristic symptoms of the disease, and if the animal recover subsequent inoculations of this micro-organism no longer produce any injury. The animal has become

Digitized by Google

protected against the disease, and there is abundant clinical evidence to show that in the case of the majority of infectious diseases the immunity lasts for many years. The pathogenic organism of the same disease cultivated outside the body produces a toxin which when administered to an animal likewise reproduces the symptoms of the disease, and if the animal recover, and further quantities of the toxin are successively administered, an immunity may be acquired so great that the animal suffers but little inconvenience when 50 times a minimum lethal dose or even a larger quantity of this toxin is now administered to it. The immunity acquired in the latter case is, however, only of short duration. I do not know if the duration of it has been defined with any of the toxins of disease, except with the toxin of diphtheria, and Roux and Klein have shown that with this toxin it lasts only from 5 to 7 days. Enough at least has been done to show that it is brief when compared with the immunity produced by the microbes from which the toxins had originated, and Klein remarks that a serum which may be relied on to afford any durable protection is still a desideratum. It is also interesting to note that Monckton Copeman has found that lymph filtered so as to remove from it all solid particles, and therefore presumably all micro-organisms, can produce only a briefly lasting protection against unfiltered vaccine lymph of normal potency. In the case of the venoms of serpents—which in composition and in other important respects are analogous to the toxins of disease—the duration of immunity has, however, been defined; and experiments have shown that if an animal be protected so as to survive the minimum lethal dose of the cobra venom, the protection produced against the same dose of venom does not last longer than a few hours; and even when the process of the immunisation has been carried so far that the animal can survive four times the minimum lethal the protection against this dose of venom exists for only 30 days

The protecting substance, antitoxin or antivenine, which appears in the blood after inoculation with pathogenic microbes, or after the injection of toxins or venoms, is chemically unstable and is subject also to the general processes of elimination. Its presence in the body, even when the quantity of toxic substance to which it owes its origin is greatly above the quantity of toxin which has been elaborated in a case of infectious disease by the pathogenic organisms of that disease, is to be measured by days only; and, nevertheless, the protection produced in a patient by an infectious disease may apparently endure for a lifetime, and the immunity from small-pox gained by vaccination for at least seven years. It appears to me impossible to explain these contrasting facts on any other supposition than that in the instances of prolonged immunity successive supplies of the antitoxin of the disease, or of small-pox, must be furnished to the body during the time that protection continues. It is not possible, however, that these supplies could emanate from the pathogenic organism itself, for the life of the host would not endure were they retained in the body in their condition of original virulence. Jenner himself believed that vaccinia is a modified small-pox. The microbe of small-pox, like all other microbes, is greatly influenced by its surroundings. When transferred from man to the calf it is now known that it may gradually acquire the characteristics of vaccinia and elaborate substances which reproduce in man the protective effects of inoculation with human vaccine. The microbe of small-pox, therefore, has obviously become so modified that while it can no longer produce a virulent toxin it still retains the power of elaborating a protective antitoxin and also retains sufficient vitality to reproduce its like through many generations in the human body. Evidence pointing in the same direction had been obtained with other pathogenic microbes. Pasteur found that the microbe of fowl cholera when treated in a certain manner can have its virulence greatly lessened and if it be then injected into the tissues of fowls only slight poisoning is produced. From fowls thus treated microbes are obtained also capable of producing only slight poisoning and inoculations can be carried through a successive series of fowls with a like result. Each of these fowls had by this inoculation with a weakened or attenuated microbe become protected against the original and virulent microbe.

In the case of the pathogenic micro-organism of anthrax this great pioneer in the field of the microbian etiology of disease discovered similar facts. If grown outside of the body at a temperature of 42·5°C. for eight days this microbe could no longer produce the disease in susceptible animals, but, notwithstanding, it endowed them with a certain degree of protection against the original virulent microbe. Similar results were obtained with the microbe of hog fever and it is important to note that a duration of immunity exceeding that known to be produced by any toxin was obtained, for the protection following inoculation of the attenuated microbe lasted for at least one year. These instances are sufficient to show that immunity equally with poisoning is dependent upon a soluble substance produced by the micro-organisms; that the duration of even a high degree of immunity resulting from the introduction into the body of the immunising substance as distinguished from the microbe is only of brief duration; and, accordingly, with the existing evidence it is impossible to account for the prolonged immunity following upon the recovery from many infective diseases or from inoculation with vaccine lymph, otherwise than by assuming that so long as immunity continues the microbian sources of infective disease continue to exist in an attenuated and otherwise modified form in the protected body. Attenuation for the purposes of protection would therefore appear to be essentially a process in which the condition of life of the microbe is so altered that its capacity for manufacturing poisons is weakened or destroyed, while its disease-preventing properties are retained. Unless by education we can so tame and civilise a pathogenic microbe as to subdue its virulent and hostile disposition, while at the same time its beneficial and protective properties are left unimpaired, the hope of obtaining—as for plague, cholera, and tubercle—immunising vaccines equal in efficiency to the lymph of vaccinia will probably never be realised. The theory which I have suggested implies that long-enduring protection from infective disease cannot be obtained by the introduction into the body of either the poisonous or the immunising products of microbes—the toxins or antitoxins—but only by inoculation of such microbes as are capable in the body of assuming a non-virulent form or of microbes already converted into this form.

I would here point out that, however highly we may value the objects and successes in some important directions of the experiments of Dr. Monckton Copeman and others on the effects of glycerine upon vaccine lymph, it must not be overlooked that the powerful microcidal action of glycerine upon the contaminating organisms of this lymph may, in the course of time, weaken or even destroy the activity of the specific organism by which the long-lasting protection against small-pox is produced. In the case of some diseases it is possible that the modification of the pathogenic power of the micro-organism necessary to convert it from a poison-producing to an antidote-producing agent cannot be accomplished in the body. Thus may be explained the failure of certain diseases to protect the body from subsequent attacks of the same disease, well recognised in the instances of pneumonia, influenza, diphtheria, rheumatic fever, erysipelas, and tubercle. On the other hand, the microbes of other diseases may in small numbers, and attenuated both in virulence and in power of conferring protection, persist in the body after convalescence has been established and actually render it not only more susceptible to fresh infection, but also to a recurrence of the disease by auto-infection. Results obtained by experiments with toxin and venom support the former possibility, for owing to some as yet unexplained individual peculiarity an animal which had received a number of successive doses of toxin or venom, each considerably below the minimum lethal, instead of having thereby acquired protection, may unexpectedly exhibit serious symptoms of poisoning and may even die when it receives a dose considerably below that required to produce death in an animal which had not previously received any toxin or venom. The probability of the second event is supported by the well-known effects upon the life and pathogenic power of microbes of changes, even although slight, in the conditions to which they are subjected. A change in temperature, the addition to or removal from the fluid in which they are grown of a minute quantity of a chemical substance, may convert a non-virulent form of a pathogenic organism into a virulent form. Similar causes may outside the body also render moderately or intensely virulent a previously non-virulent microbe, and thus may be explained variations in the severity of epidemics as well as the occurrence of outbreaks of infectious disease not originated by infection from any previously existing case. The dependence of microbial existence upon the composition of nutrient

Digitized by Google

media may also partly account for the age liability, which forms so conspicuous a feature in the history of such infectious diseases as scarlet fever, measles, and whooping-cough. Further, pathogenic microbes, attenuated as to their virulence but not as to their protective power, may enter the body and render it immune by a process of accidental vaccination; and thus may be explained, without recourse to such unsatisfactory phrases as individual or racial peculiarities, well-authenticated examples known to all of us, of repeated exposure to infection without the production of disease and of the immunity enjoyed by the inhabitants of towns and districts daily subjected to the virus of typhoid fever, malaria, or yellow fever. These are not mere hypotheses unsupported by experimental data. Describing the results of his experiments on anthrax Pasteur states that when fowls are inoculated with the virulent microbes of this disease they remain well until they have been cooled down to a subnormal temperature; and in the earlier stages of the poisoning thus induced, if the temperature be again raised, the symptoms of anthrax disappear and the fowls recover. Anthrax microbes, as well as those of fowl cholera, if cultivated at a temperature between 42° and 43° C., acquire varied degrees of lethality according to the age of the culture, and the microbes of each variety of lethality can be almost indefinitely reproduced by maintaining certain conditions of cultivation. If microbes so grown as to be no longer able to produce anthrax in rabbits are first inoculated in a successive series of experiments in young, and for that reason extremely susceptible, rabbits, and if the microbes obtained from the last of the series are then inoculated into somewhat older and finally into adult rabbits, the original virulence of the microbe is found to have been regained. "The work in my laboratories," he states, "has established that pathogenic microbes are not morbid entities. They can assume various forms of physiological activity, depending on the media in which they live and multiply. As a consequence one can modify their virulence. It can be exalted or enfeebled and each state can be fixed." Impressed by the far-reaching possibilities suggested by these and other fruits of his fertile imagination it is not astonishing that the great enchanter whose divining rod of science had thus thrown a clear light on the mysteries of centuries should exclaim: "The hour has now arrived when we may enter the enchanted grotto full of priceless treasures."

THE ORIGIN OF THE PROTECTION-PRODUCING SUBSTANCES.

Passing now to consider the origin of the protection-producing substances—antitoxins or antivenins—it is important to bear in mind that the symptoms of a pathogenic disease, the toxic phenomena by which it is characterised, are, with a few doubtful exceptions, directly caused by the poisons generated by micro-organisms and not by the micro-organisms themselves. The production of microcidal agents does not, therefore, in connexion with this question require consideration, but it may be pointed out that there is evidence of the production both by toxins and by micro-organisms of substances specially unfavourable to the vitality of the micro-organisms themselves. The explanation of the production of antitoxin in the body, whether following the introduction of virulent microbes or of toxins entirely free from microbes, has generally been explained by a reaction occurring in the tissues of the body, whereby either a proliferation of leucocytes and the production by them of the protecting substances is excited or the normal cells of the body are stimulated in such a way that they secrete the protective substance. I have to some extent already discussed the question of phagocytosis, which is involved in the first explanation. To the objections that have been stated there are others which can be derived from the results of observation and experiment. In many instances, when immunity to a high degree has been produced by venom, no increase can be found in the number of leucocytes immediately or at varying periods after the subcutaneous injection of large though, in the circumstances, easily tolerated doses of venom. Further, when one-half more than the minimum lethal dose of venom is mixed outside of the body with antivenin, and the mixture injected into an animal, the quantity of antivenin required to prevent this lethal dose from producing death is only the quarter of a cubic centimetre, whereas if the antivenin be administered half an hour before the same dose of venin so much as 3 cubic centimetres are required. That is to say, in conditions which are the more favourable for the proliferation of leucocytes, or for the production by them of protecting substances, the antivenine is less efficient as a protecting agent than when the conditions are much less favourable.

As to the second theory, often termed the reaction theory, it is also opposed by the experiments I have last mentioned, but equally so by the fact that a high degree of immunity can be produced by an appropriate adjustment of doses without any observable reaction occurring. Even when a distinct reaction, such as an elevation of temperature, is produced during the process of immunisation, the production of the reaction is in itself of no other significance than that a dose of an active substance sufficiently large to cause an observable effect had been administered. The subject, however, is surrounded by difficulties, not a few of which have arisen from the attempt to obtain an explanation without separating the influence of the microbe from that of the toxin, with the result that biological conceptions have perhaps been introduced unnecessarily into the consideration and discussion of the subject. As a contribution to the solution of the problem I would advance the following facts. Although searched for no proteolytic or fermentative action has been discovered in the case of any toxin or venom; by subjection to certain external influences, such as elevation of temperature and the influence of electric currents and of certain chemical reagents, toxins and venoms may have their poisonous action destroyed while the immunising or protective action is retained; and toxins have been found actually to contain protective or remedial substances along with their toxic ingredients, as shown, for instance, by Hunter in the case of the toxin of tubercle.

These considerations suggest that the protecting substance originates directly from the toxin or is indeed an ingredient in its complex composition. The suggestion is supported by experiments which show that the degree of protection artificially produced in an animal—for it is, perhaps, not unnecessary to state that protection and immunisation are only relative and not absolute—is proportional to the total quantity of toxin or venom introduced, rather than to the amount of reaction produced in the animal by any of the several administrations. The remarkable facts which have been described in connexion with the stomach administration of venom, obtained also by Ehrlich and Kobert with the somewhat similar bodies, abrin and ricin, and by Valli with the virus of hydrophobia, seem likewise to receive their most satisfactory solution on this supposition. A dose of venom several hundred times greater than is requisite to produce death by subcutaneous injection fails when introduced into the stomach to produce any poisonous symptom whatever, but still so protects the animal that considerably more than the minimum lethal dose may now be subcutaneously administered without producing death. It is difficult to account for these facts otherwise than by assuming that the venom while in the alimentary canal had been subjected to a process of analysis, as the result of which its toxic constituents had been separated from those which are antitoxic or protective; and while the former had either been destroyed or had failed to be absorbed the latter had passed into the blood in sufficient quantity to protect the animal against otherwise lethal administration of venom. There are undoubtedly many facts still required before a convincing explanation can be formulated of the origin of the antitoxic substances that appear in the body after the reception of pathogenic or other similar toxins; but the facts already ascertained appear to indicate that the antitoxic or immunising substances originate not from vital reactions upon constituents of the body but from the toxins themselves, being produced by chemical changes in them, or being actually among their normal ingredients. The question is not only of scientific interest, but it has also a practical bearing. The manufacture of the immunising substance is attended by much difficulty. A satisfactory antitoxin can rarely be obtained until a tedious process, extending over several months, has been followed. Anti-pneumococcus serum requires so long a time as six months, the immunising serum of yellow fever from twelve to eighteen months, and the nearest approximation yet obtained to a satisfactory protecting serum for tubercle the almost impracticable period of several years. Were it recognised that the antitoxin originates directly from the toxin the preparation of it would be freed from existing difficulties and mysteries and after some necessary chemical research it could be produced in the laboratory and thus brought into closer relationship with ordinary medicinal substances. Any generalisation in

Digitized by Google

medicine, while it may serve the useful purpose of emphasising advancement in knowledge, must remain barren of practical result unless it also supplies general principles as well as specific indications for treatment. It may with some confidence be stated that the doctrine of the toxic origin of disease does not fail in these respects.

In the case of ordinary poisons it has been well established that recovery is largely promoted by hastening the removal of the poison from the body, especially by means which it is the province of pharmacology to indicate, and the eliminative treatment which has long been followed in many diseases thus finds in their now definitely established toxic origin a sufficient explanation and justification. Clinical and experimental evidence, not restricted to ordinary poisons but gained also from the study of the effects of toxins and venoms, has taught us that treatment should also include the adoption of measures for increasing the resistance afforded by the body to toxic and morbific processes. If a dose of venom below the minimum lethal be administered to an animal and after all obvious symptoms of poisoning have disappeared this dose be followed by a second, also considerably below the minimum lethal, the animal may die, although each dose was in itself insufficiently large to cause death. If an animal has been inoculated by a non-lethal quantity of the virus of a recognised disease such as anthrax, and after recovery has apparently been established if a non-lethal dose of the virus of another disease be inoculated, death will follow the inoculation of the second dose, although that dose is quite insufficient of itself to produce death in an animal which has not previously been thus treated. In both cases the power of resistance has been so weakened by the first and apparently recovered from administration that a quantity of virus in itself insufficient to cause death now succeeds in doing so. From such examples the explanation is found of the widely prevalent employment of means to increase the strength or resistance of a patient, of the value of tonics and foods and of fresh air and light, not only in promoting recovery from illness, but also in actually preventing a fatal termination. Expressed in another form these constitute means for slightly increasing for any given degree of disease the minimum quantity of the disease-producing influence or substance required to produce that degree of disease. These as well as other methods of treatment that might be referred to do not, however, directly affect the true cause of the malady. Hitherto this cause could be counteracted or opposed only in the instances of the well-known poisons which are dealt with by toxicology and of a very few diseases such as ague and syphilis, in which the cause was surmised, without being proved to be a poisonous substance; and in substances fitted to antagonise these poisons by chemical combination or, though only to a limited extent, to counteract their effects by physiological processes, therapeutics has possessed satisfactory resources. By the demonstration of the production of many diseases by toxins generated by micro-organisms the opportunities for the application of these principles has been greatly extended. Diseases whose treatment had previously rested on an uncertain basis have now been brought into the range of rational therapeutics, and it has been shown that morbific processes which had already become so definitely established as to display serious symptoms can be entirely arrested and, above all, that illnesses which would otherwise inevitably terminate in death may be so perfectly controlled that the fatal termination can be prevented and recovery ensured. A dose considerably above the minimum lethal of the toxin of tetanus is administered to an animal. Several hours after the administration, when symptoms of tetanus had manifested themselves, the antitoxin of tetanus derived from an animal which had been immunised against the virus is injected under the skin and in a short time afterwards the symptoms of the disease disappear and the animal recovers. A dose of cobra venom sufficient to cause death in two or three hours is administered to an animal. The venom illness is developed and while it is quickly advancing to apparently an early death a dose of antivenin—the blood serum of an animal highly immunised against this venom—is administered and by-and-by the symptoms become mitigated and in a few hours the animal, which otherwise would certainly have died, is restored to a perfectly normal condition. By this antidotal treatment, further, not only is disease arrested and even death conquered, but the structural alterations in the muscle fibre and elsewhere that the tetanus toxin produces, and also the acute and rapid changes in the parenchyma of the kidney, characterising the poisonous action of serpents' venom, are altogether prevented from occurring. How are these marvellous therapeutic or curative effects to be explained? The explanations that have been advanced are essentially the same as those applied to the production of immunity and they have already been disposed of in the discussion of that subject. Specially bearing on the therapeutic aspect of the question are the further considerations, that antitoxins are destitute of any distinct physiological action, and, founding on Declory's recent work on antivenine, antitetanine, and the antitoxin of diphtheria, they have no influence on the processes of ultimate nutrition. Their curative action cannot therefore depend on physiological antagonism and it is highly improbable that it has any biological basis whatever.

Referring again to experiments made with serpents' venom, when this venom in lethal quantity is mixed in a test tube with a small quantity of antivenine the venom almost instantly loses its toxic power. Further, if the smallest quantity of antivenine required to produce this change after contact for a definite time with a lethal quantity of venom be determined, it will be found that if the time of contact is lessened this quantity of antivenine is no longer able to remove the toxicity of so large a quantity of venom. When, again, venom is injected under the skin of an animal at the same time as, but in a different position from, the antivenine, the quantity of the latter required to prevent death is for the same dose of venom about twelve times larger than when the two substances have been mixed together before they were injected. Such distinctions are difficult of explanation otherwise than by supposing that a combination, chemical or mechanical, is effected between the antivenine and the venom, for they indicate that when the conditions are the more favourable for ensuring contact between the antitoxin and the toxin the antidotal action is more powerful than when the conditions are less favourable for this contact. This view is also supported by the fact that if the antivenine be administered after the venom the dose of the former required to prevent death is enormously larger than when the two substances are simultaneously administered after they have been mixed together outside of the body. In the case of antivenine and venom the difference is as great as 1 to 1200. This experimental result, harmonising altogether with a physical as distinguished from a biological explanation of the antidotal action of antitoxins, emphasises the lesson, gradually receiving acceptance in practice, that for the effective treatment of an infectious disease the quantity of antitoxin must be a very large one, and at least 1000 times greater than is indicated by the *in vitro* experiments by which their antidotal power has usually been determined and standardised. For this reason the antitoxic serums frequently in use at the present time must be regarded as too dilute solutions. It is indeed probable that the process of immunisation, even when carried to its utmost limits, is incapable of producing antitoxic serums sufficiently powerful, in doses which can be administered, to cure a patient suffering from the effects of a large lethal quality of toxin. Chemistry, however, has as yet left almost untouched the investigation of antitoxic serums, and it may confidently be expected that when more knowledge has been obtained of their chemical composition this difficulty will be overcome by the separation of the curative from the worthless ingredients.

THE PRESENT POSITION OF SERUM-THERAPEUTICS.

By such results as are exemplified in the experiments that I have described a new era has been originated in practical medicine. Considering how limited were the means—if, indeed, they previously had existed—of actually preventing death when the fatal disease conditions were already present a special fascination attaches itself to the subject of antidotal treatment of disease, the newly created serum therapeutics. It has merely entered the first stages of its development and has had to contend in its applications to human beings with the difficulties presented by the presence of undiscoverable amounts of disease toxins diffused by living generators of it, which are present in the body in unknown quantities and in varying toxic potentialities. The results already obtained are, however, of much value. Diphtheria has had its case mortality reduced from 70 per cent. to 26 per cent., or, according to another estimation, from 40 per cent. to 8 per cent.; hydrophobia has been so far brought under therapeutic control, by means which have not as yet been developed to their full efficiency, that its mortality has shrunk at least from 16 to 1 per cent.; the prognosis of tetanus has been deprived of much of its gloomy forebodings; the cure of pneumonia, of tubercle, of erysipelas,

Digitized by Google

and of septicæmia is on the eve of being realised; a complete demonstration has been obtained of the power of anti-venomous serums to prevent the toxic and lethal effects of venoms; and the experimental data are being surely accumulated for completing the greatest triumph of preventive medicine by the discovery of an antitoxic serum for the cure of small-pox.

These, however, are to be regarded as merely the first fruits—in some cases requiring further maturing by the light of science—of the ample harvest which is ripening. Their acquisition at the same time has been sufficient to supply materials for constructing in perfect outline the doctrine of the toxic origin of disease to which I have ventured to ask your attention. This doctrine has at least the merit of being able to bind together in one harmonious unity the conception of the actual nature or essence of a large number of diseases, including those which most urgently demand consideration. It supplies a simple and intelligible basis for treatment. Under its directing influence it may confidently be anticipated that medicine will reach a position of definiteness previously unattainable; and, above all, that the healers of disease will have their resources rendered more effective and beneficial for mankind.

Address in Surgery:

THE PRESENT POSITION OF SURGERY.

Delivered at the Annual Meeting of the British Medical Association at Edinburgh, July, 1898,

BY THOMAS ANNANDALE, F.R.C.S. EDIN., F.R.C.S. ENG., F.R.S. EDIN.,

REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH; SURGEON TO THE EDINBURGH ROYAL INFIRMARY.

MR. PRESIDENT AND GENTLEMEN,—I desire to join my colleagues in offering you a most sincere welcome to Edinburgh, and I desire also to express the hope that you will all be able to look back upon your visit here as pleasant, interesting, healthy, and profitable both to mind and body. When asked by a deputation of my colleagues in Edinburgh to give the Address in Surgery I felt that an honour had been very kindly and courteously shown me; but in accepting this offer I also felt that I had undertaken a responsibility—a esponsibility which called upon me to speak to this distinguished audience as a representative of Scottish surgery. This responsibility was all the more serious to me for my friends know well that I am more ready with the knife than with pen or speech, and as my daily life for many years has been to lecture and demonstrate to students as babes entering the profession I had some fear that I might be offering to you as men and kings in the profession baby's food. My first difficulty was to select a text on which to address you. I might have offered you some of the results of nearly forty years of active hospital and private surgical practice, but I felt that an account of any such results was more fitted for the departmental sections. I also at one time thought I might have endeavoured to prove to you—and I think I could have proved to you with success—how much Scottish surgeons and Scottish work have assisted in the development and improvement of surgical practice, but with this thought there suddenly came to my mind the old Scotch saying, "Ye'll hae a guid conceit o' yersel," and accordingly I at once dropped the idea of Scottish self-glorification. After consideration it seemed best to me to take some more general text, and accordingly I decided to offer you a few remarks upon the present position of surgery. It must, I think, be universally acknowledged that the present position of surgery is of the highest. There are now few diseased conditions in which surgery does not play a very essential part in connexion with treatment, and there is scarcely a single organ of the body, internal or external, which is not the subject of successful surgical procedure. The brain, the organs of the chest, abdomen, pelvis—many of which were so long looked upon as belonging solely to the province of the physician—are now shared, if not principally absorbed, by the surgeon as regards the relief or cure of their diseases.

It has sometimes occurred to me that on not a few occasions my esteemed colleagues the physicians have a strong longing to be surgeons for the time being, in order that they might be able to carry out some surgical procedure which their experience has taught them to be more efficacious than medicine. For the sake of convenience and partly also, as is known to some here, that a discourse in this country is not considered complete unless delivered under from three to twelve heads, I propose to treat my subject under certain heads. In consideration for your feelings and time I propose to confine these heads to three, the minimum number allowed, and to speak of present surgery in (1) its scientific aspect, (2) its practical aspect, and (3) its moral aspect.

I.—ITS SCIENTIFIC ASPECT.

It must at the outset be acknowledged—and acknowledged with gratitude—that the marvellous advances in connexion with present surgical practice are largely indebted to those who have diligently, honestly, and successfully carried on experimental and other research in connexion with the sciences of chemistry, physiology, bacteriology, anatomy, and pathology. We, as surgeons, look forward hopefully to receive the continued aid of these gentlemen in still further promoting our art, and it should be our duty to encourage and assist in every possible way all such scientific work—work which in connexion with surgery can only be considered to be in its early infancy and which will require much care, accuracy, and close industry to establish its steady and sure growth. I would now refer to some of this scientific work which has so benefited surgical practice. To speak of the antiseptic system at the present time is to speak almost of ancient history, but two reasons prompt me to refer to it. First, because it was in this school that its distinguished author carried on those carefully conducted and original researches and experiments which led him to suggest this great principle. Secondly, because I have lived long enough to have had experience of three epochs in connexion with surgical wounds. As a young apprentice more than 40 years ago I witnessed the dressing of wounds by the application of layers of ointment, the edges being brought together by sutures of thick silk and the arteries secured by ligatures of the same material, the ends of the ligatures being left hanging out of the wound and acting much like setons. As a dresser under the great Syme I learnt the simpler methods of water dressings and of dry dressings, and, lastly, as a pupil and colleague of Lister I had the good fortune to follow the various stages of the developments of the antiseptic treatment. In the first of these epochs I gained a large experience in connexion with septic suppuration, hospital gangrene, pyæmia, and septicæmia, all of which conditions were common and frequently led to fatal results. In the second epoch my experience of septic suppuration, pyæmia, and septicæmia was small in comparison, but still too common. In my third and present epoch such experience has been reduced to a minimum.

In the early stages of the antiseptic suggestions failures undoubtedly occurred, but such failures when honestly investigated were important as lessons, and the consideration of their causes did much to establish on a successful basis the great principle. There were some who, ignoring the principle of the antiseptic treatment and also ignoring the established principles of surgery, preached and practised that the mere application of carbolic acid or other antiseptic lotion was all that was required, and when such treatment was unsuccessful condemned the whole system. Let me quote a sentence from an address which I gave when appointed Professor of Clinical Surgery in this University, now twenty-one years ago: "It is not the mere application of carbolic acid in one form or another which constitutes the antiseptic treatment, but the true antiseptic surgery is that which is the result of many years' patient, thoughtful, and scientific research; of vast, laborious, and expensive experiments, and of much and valuable time spent in clinical observation on the part of Mr. Lister." I confess that I was one of those who, while carefully watching the progress of Lister's work, and thoroughly believing and greatly admiring his great scientific abilities, was at first cautious in accepting all the details of its practical application because I felt that these were somewhat complicated, and it was certainly a great relief to my mind and to the minds of many others, I am sure, when it was found that in actual practice many of these details could with safety to

Digitized by Google

the principle be much modified and simplified; and, further, I had learnt from experience that even with the use of antiseptic treatment the ordinary principles of rest, avoiding causes of irritation, and attention to the general health must not be ignored. I know that no one rejoiced more than Lister himself when it was proved that his great system could be successfully simplified and so used under circumstances which formerly made it difficult or impossible to carry out. But while the external application of antiseptic means and precautions is now thoroughly established upon a simple and at the same time efficient basis, it must not be forgotten that injurious organisms enter the body and tissues by other channels than through external wounds or breaches of surface; and therefore it is that the science of bacteriology becomes so important a study in connexion with disease and with the results of injuries and surgical procedures. It is to a further study and knowledge of this science—which must be considered as still in its infancy—that surgery as well as medicine looks for more light in connexion with the causation and treatment of diseased conditions.

Although experimental and pathological research and clinical observation have already done something to explain and determine the action of certain organisms the particular manner in which these organisms cause in one case no result and in others injurious results cannot be considered as proved. We certainly have learnt certain facts: first, that organisms of various kinds gain entrance into the tissues or organs of the body; secondly, that some special condition of these tissues and organs favour their development and multiplication. Such organisms vary much in form, source of origin, situation where chiefly met with, conditions under which they develop or are destroyed, and the special effects which they produce. In the majority of instances the bad effects are produced not so much by the multiplication of the organisms themselves as by poisons or toxins caused by their presence or behaviour in connexion with the tissues. Further, it would appear that the resulting toxin may not itself produce the poison, but give rise to chemical changes and products which are the real cause of the injurious results. It is also an interesting fact that the presence of more than one form of bacillus may either increase or destroy these injurious results. The conditions of the tissue or soil in which the organisms settle has much to do with the results caused. Individualism, age, constitution, the general condition of the patient, and any local condition, more particularly any condition which interferes with the vitality of the tissues, influence much the action of organisms. The resistance of the tissues to the injurious effects of organisms depends upon the condition of these tissues, upon the activity of the organisms, and upon the amount and virulence of the toxins developed. It appears that it is the spores of organisms which most resist destruction, and as these spores may germinate not only in the tissues but outside the body they act as a serious source of infection. From the facts I have just stated it will be judged what difficulties arise in connexion with the study of bacteriology, and consequently with the treatment of the injurious results produced by the numerous organisms which invade and affect the human body. Bacteriological experiments upon the lower animals may in some instances aid us, but the conditions of the lower animals are not always the same as those of human beings, and therefore results obtained in the former are not always safe guides as regards results in the latter. Continued careful study of anatomy and pathology and accurate clinical observation should do something to increase our knowledge, but I venture to think that much of our future trust for light must be in connexion with physiological chemistry, which we hope may be able to teach us more of the origin, causation, and behaviour of the various toxins and of the action of the tissues in connexion with them, so that we may be able to counteract their injurious effects by appropriate treatment.

At the present time we endeavour to treat the general effect of these toxins either by the administration of remedies supposed to produce a general antiseptic effect—but it cannot be said that such treatment has proved satisfactory except in a limited number of cases—or by the introduction into the tissues by subcutaneous injection of so-called antitoxins. This latter treatment has met with an encouraging amount of success, especially in certain directions; but its position is still uncertain and much further experience is required to place it on a safe and reliable foundation. All who have employed the antitoxins in connexion with surgical conditions must have encountered this uncertainty as to their action. My own experience is that though some severe cases of septicæmia have recovered after the injection of an antitoxin other cases very similar have recovered without any antitoxin being used. I would suggest that another important subject for further study is the physiological action or connexion between one tissue or one organ and another. May not further experience of this connexion help us in carrying out treatment based upon this connexion? Take, for instance, the suggestion of Beatson for removing the ovaries in cancer of the female breast, incurable by other means. Having thought it my duty to test this suggestion I carried it out in three typical cases, and my experience and the experience of others who have tried this procedure has been that though the disease was not cured the removal of the ovaries had certainly some influence upon the diseased local condition. I venture also to suggest that as a possible and further addition to treatment some more careful work should be devoted to the action of drugs upon the toxin poisons, such drugs being introduced either by the mouth, by subcutaneous or intravenous injection, or by inhalation. We know that large quantities of saline fluid may be injected into the veins with safety and it is therefore not unreasonable to suppose that other solutions of a non-irritating and antiseptic nature may be similarly employed. The remarkable results obtained by thyroid extract should be an encouragement to us in this respect and it has already been proved that certain vegetable products act as powerful antitoxins. If it can be discovered that certain drugs can be safely and successfully used as antitoxins it will much simplify our treatment, for such remedies would be more easily and more certainly handled than the antitoxins now in use. The treatment of sarcoma or other new growths by means of toxins is another subject of great interest to the surgeon. The results obtained by Coley and others by the mixed toxins of streptococcus and prodigiosus do show some hopes, for under the use of these toxins growths have undoubtedly disappeared, but I think that all who practise surgery will agree with me when I say that sarcomas and other growths do occasionally undergo a check in their development and even disappear without any apparent cause. In all probability these occasional occurrences are the result of some physiological or bacteriological action which is not perceptible.

Reference to the scientific aspect of surgery would not be complete without some notice of the "New Photography." Ordinary photography has always been of great assistance to surgeons and will continue to be so for the illustration, progress, and record of many of their cases, but its new and latest development has already proved to be of the greatest service in diagnosis and consequently in connexion with successful treatment, and an improved development of it will no doubt add still more to the success of surgical practice. The scope of this department of science is a very wide one and by its means we may add much to our knowledge of osseous development and growth, of the relation and position of internal organs, and of the actual condition of diseased parts. In connexion with many surgical conditions, and especially in connexion with injuries of various kinds, this photography is invaluable.

In leaving this, the scientific portion of my address, I desire again to express the indebtedness of practical surgeons to those discoverers and workers in science who have by their honest and accurate observation obtained results which have done so much to improve our practice and so to render our treatment more successful.

II.—ITS PRACTICAL ASPECT.

To one like myself who, as apprentice, student, and surgeon, has for more than forty years followed the practice of surgery its steady and remarkable progress is a most interesting study. In watching this progress it not infrequently appeared as if perfection in some particular procedure had been reached, but a little more experience or a little more observation gave rise to a suggestion which entirely drove the so-thought perfection from the field and opened up a new and important practice with resulting benefit to suffering humanity. There are few surgical procedures which have not undergone some change and marked improvement since I first commenced the study of surgery and the number of new procedures suggested would require many pages even to enumerate them. While not a few of these suggestions have become established in practice many others, being founded on incorrect or ignorant principles, have perished and deservedly so. To myself and to others it has often been interesting to observe the gradual development

Digitized by Google

of some procedure or treatment; a suggestion made by one surgeon would lead to an improved suggestion by another and this process of improvement might again be taken up by a third or fourth until at length its thorough success was established. My Scottish modesty prevents me from referring to work of my own, but it will always be to me a feeling of satisfaction that in connexion with my very special opportunities for experience in surgical practice I may, in some small way, have been able to assist in adding to or originating such suggestions and improvements. I know I shall be excused if I here refer to the fact that to the great Syme I owe my opportunities for the study and practice of surgery, and it was in connexion with my intimate association as his assistant for more than ten years that I learnt how to attain and how to exercise the qualities which are the essence of good and honest practice. Another personal incident I may be allowed to mention is, that as a baby I once rested in the arms of the great surgeon Liston, who was the favourite chief of my father, and although at that time I received no bodily nourishment from him in after-life I obtained much surgical nourishment from the study of his writings and work.

The advances in our scientific knowledge, combined with extended and more accurate clinical observation, have, as has already been stated, assisted much in the improvement of practical surgery, and the development of what I would designate honest specialism must also be looked upon as adding to our practical resources and treatment. If asked to define any special characteristic which will apply to the practice of surgery at the present day I would be inclined to say simplicity—antisepticity, of course, being granted—a simplicity in which is included operative procedure, instrumental assistance, and after-treatment. It is true that from time to time new procedures and new instruments are suggested, but as a rule it will be found that if practical surgeons adopt and employ them they are in the direction of continued simplicity with some addition to their efficiency. In a general address such as this a reference to all the improvements which have taken place and are taking place is quite unnecessary, as such improvements must be well known, or should be known, to all who desire to carry on with success the active practice of surgery. For such knowledge we have not only our own experience to aid us, but we have to thank the medical press and the many distinguished authors who by their books and papers bring the results of their own experience and observations and researches under the notice of the profession. Although so many and so great changes have taken place as a result of the advances in the departments of science already referred to it would be very wrong to ignore the work of those surgeons who are no longer with us. Many of these surgeons showed a knowledge and wisdom and forethought of conditions and procedures which have stood the test of time and still remain sound and correct as monuments of their genius. This knowledge was principally the result of shrewd and careful clinical observation and reasoning, for they had little or no scientific aids to help them, and their success under such circumstances should be an example to all of us to make every use of our clinical opportunities and to observe closely, carefully, and honestly. But the practice of surgery has not only reached a high standard of improvement, but it has much widened its area both as regards the number of its procedures and the number of those who practise them. This is scarcely the time or place to discuss the exact relationship between surgery proper and what is called gynæcology. Of late years these departments have been gradually merged into one another, so that the line of demarcation between them is scarcely apparent. Both are really surgical procedures and both require for their proper and successful performance that training and those qualities which make the good surgeon. That physicians under the designation of gynæcologists should now become operating surgeons is perhaps only a little return for the fact that surgeons have so extensively and successfully invaded the province of physicians, and as time goes on some balance may perhaps be arrived at which, while guarding the interests of the public, will satisfy the representatives of medicine and surgery.

In this greatly improved era of practical surgery it is well perhaps to suggest a caution, for there is undoubtedly a tendency—and more especially in the case of some of our younger colleagues—to be too ready to resort to surgical procedures. When greater risk was attached to operative procedures surgeons young and old had, for the sake of their patients and their own reputations, to take into account these risks even in comparatively slight operations; but now that so little risk attends operations they may be undertaken without due consideration of all the circumstances or necessities of the case. I would as a senior colleague venture to remind my younger friends that Nature, with perhaps some little non-operative treatment, will do much, and that no operative procedure should be suggested or practised until the case has been thoroughly studied and found to be unrelievable by other means.

As a practical surgeon in this, the Edinburgh School of Medicine, it may be expected that I should refer to my experience of anæsthetics, and I accordingly express the opinion that chloroform holds the field as the best general anæsthetic in connexion with surgical procedures; and although I have met with a few fatal results from its administration I have most thorough confidence in its safety if carefully used and its effects diligently watched. Perhaps the best test of my confidence is the fact that having a few years ago suffered from a poisoned finger received when operating I required to take an anæsthetic on several occasions in order to have deep incisions made for the relief of extensive suppuration. The anæsthetic I took was chloroform, and it was administered according to the "open" method by one of my assistants and not by any special anæsthetist. It is my opinion that fatal results will occasionally take place in connexion with all anæsthetics, and that these fatal cases may be divided into (1) avoidable, and (2) unavoidable. The avoidable ones are those which are due to careless administration or to neglect of means to prevent blood or other matters entering the air-passages, and should not occur if proper care is exercised. To avoid these risks it is essential that one person should give sole attention to the anæsthetic and watch both respiration and pulse, more especially the respiration and its nature, during the whole period of its administration. I need scarcely say that the preparation of the patient is, when possible, important. I prefer to give a small basin of plain soup about two hours before the chloroform is administered and, if the patient is feeble or the operation likely to be attended with much shock, a tablespoonful or more of brandy or whisky a quarter of an hour before the anæsthetic. In cases in which there is a risk of matters, and especially of blood, passing into the air-passages, the dependent position of the patient's head, as advocated by me in 1879, will often prevent this accident, and should it take place immediate tracheotomy must be resorted to if the symptoms are serious. The unavoidable cases are, in my opinion, the result of heart failure from fatty or other conditions and occasionally, I believe, they may be caused by cerebral conditions, as I have seen a fatal case in which the symptoms resembled most an epileptic seizure. Further, I believe that in the majority of these unavoidable cases it is impossible by any external examination prior to giving the anæsthetic to discover the condition which has led to the fatal result. I am inclined to think that the avoidable accidents are more frequent than the unavoidable, and if so it teaches us how important it is to avoid, by careful preparation and administration, anything likely to bring about an unfavourable result. I would like here to give a word of warning as to the use of cocaine in local anæsthesia, and more particularly when it is used by subcutaneous injection. My experience is that some individuals are specially susceptible to its action, and therefore, if too strong a solution or too large an amount of a weaker one is injected, the result may be faintness and serious interference with heart action. It should therefore be used cautiously and a stimulant be given, or be at hand in case of such symptoms occurring. Not wishing to weary you, I close my remarks under this head by referring to the importance of taking carefully into consideration everything likely to influence the performance or result of any surgical procedure, and when possible to first remove by proper treatment conditions likely to interfere with or to retard the recovery of the patient. It is not age or apparent feebleness which is likely to cause anxiety, but it is the condition of the organs and the tissues which should guide the surgeon, for if these be in a weak or in a diseased state they are more likely to become the soil for injurious bacteriological development and action.

III.—THE MORAL ASPECT.

I make no apology for offering a few remarks under this head, with the explanation that I employ the term "moral" in its highest and widest sense, for I am decidedly of opinion

Digitized by Google

that it becomes every member of our profession who has the true sense of relieving suffering humanity at heart and who desires to maintain the honour and reputation of his profession to speak out with no uncertain meaning in regard to every action which is dishonest or dishonourable or tends to be so. The actions and practices of so-called quacks or unqualified individuals are much to be deplored, and it is in every way desirable that legalised checks should be established so as to prevent or limit them, and more particularly in the case of the ignorant and uneducated public. If the educated public consult such practitioners—and it is not very uncommon for them to do so—they can only blame themselves should unfortunate results take place. It is, however, of practices inside the profession of which I wish to speak. It is sincerely to be regretted that in some quarters the true, honest, and high feeling which should be the standard principle of the members of our profession is in the present day partially or wholly ignored, and in consequence our profession is not always respected as it should be and its members are looked upon by some as mere humbugs, in some cases not without reason, thinking more of fees and fee accumulations than of their patients' cure or relief. Three causes seem to me to influence this much-to-be-lamented evil which has insidiously invaded our profession—(1) active competition, (2) untrained specialism, and (3) Society demands.

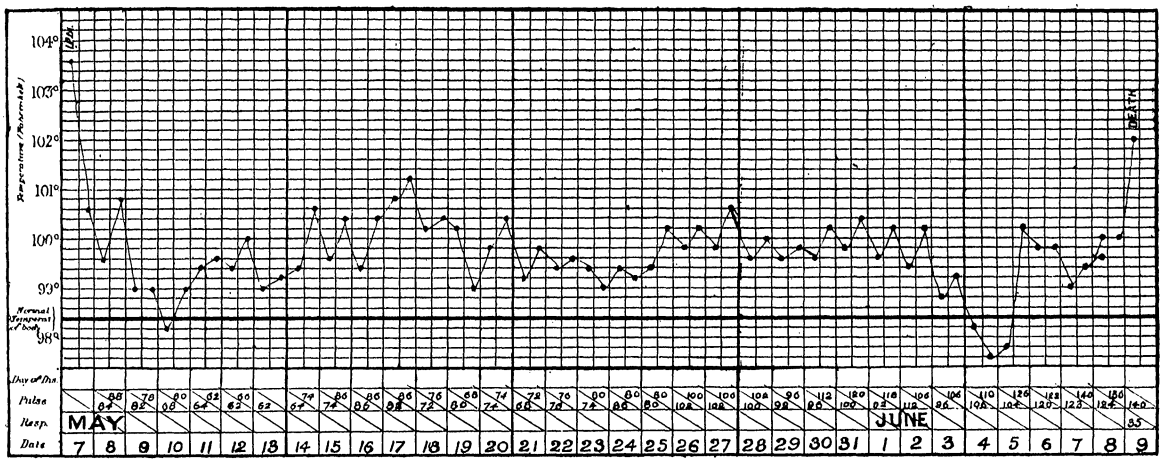
There can be no doubt that the number of medical practitioners has increased, but in connexion with the increase of the population this increase in numbers is not so great as is generally supposed. A few years ago I selected statistics in connexion with this question and, taking some of the largest provincial towns in England and Scotland, I found that the number of medical men as compared with the population was very little changed from what it had been twenty years before. The active competition therefore is, in my opinion, not so much due to the increase of medical men as to the fact that in many instances the most of the remunerative work is done by a few, which leaves much hard work and poor pay for the remainder of the profession. My suggestions for the cure of this are that those who constitute the few should be specially careful to guard and encourage the interests of the many, should not seek to secure every remunerative appointment within their reach, but should at least leave some crumbs for their less fortunate brethren.

The second cause is untrained specialism. I have already stated that honest specialism has aided much the practice of surgery, and by honest I mean such practice as is founded upon a thorough knowledge of all the different departments of the profession and upon an honest study of all the circumstances connected with the various conditions which affect the organ or organs which are specialised. Specialism in the hands of qualified members of the profession, unless practised under these conditions, is simply quackery, and quackery of the worst kind, for it is carried on by those whom the public understand to be properly educated as regards their profession. There are few who endeavour to practise their profession with integrity who have not met with cases in which mere symptoms have been treated by operation or otherwise, the real source of the diseased condition having been entirely ignored, either through ignorance or for reasons which can only be classed as contemptible and degrading to the profession. The cure for such practices is not easy, and it can only be hoped that the honest members of the profession will note such practices and endeavour to check them by exposing their real nature and by endeavouring with tact to educate the public mind to avoid those who practise them as unsafe and possibly dangerous advisers.

The third cause is Society demands. A section of the public, or I should rather say a section of what is termed "Society," has done much to interfere with the proper feeling which should exist in our profession. Men, women, and even young people read and discuss professional matters and diseases; books are published and advertised which are written more to catch the eye of the public than to advance the knowledge or reputation of the profession; a certain class of newspapers and periodicals devote one or more columns to professional subjects, and even give gratuitous advice in the form of Questions and Answers. The manners, qualifications, and doings of members of the profession are freely criticised at afternoon teas and other entertainments. One man is condemned and some supposed failures in treatment are magnified or invented, while another receives extravagant praise and many of his wonderful surgical or other procedures are lauded and not infrequently described with marvellous details added. One is glad to think that in the majority of instances the surgeon or specialist has no art or part in such proceedings and, having with justice confidence in his abilities and upright conduct, much regrets that they should exist and does all he can to prevent their occurrence. But there are some, I fear, who take advantage of such extravagant popularity and, having become the fashion, trade upon it in a manner which is not consistent with the high feelings which should influence all our professional relationships. It is fortunate that there still exist among the public in all classes of society many who are endowed with nature's nobility and good feelings and who are not influenced by the extravagant or false opinions of fashion, but who have both respect and esteem for those members of the medical profession who conscientiously devote themselves to the relief of suffering. We can all hope, but I fear hope in vain, that those members of Society who lead a frivolous, useless, and sometimes unholy life may some day realise that they are not acting as true citizens of their country or taking any proper interest in the welfare of their countrymen and countrywomen. If some of their energies, some of their time, some of their sympathy, and some of their money were employed to assist their fellow-creatures they would themselves reap reward by feeling that their lives were not altogether a selfish existence. If any member of our profession encourages or takes part in Society's ignoble life or actions he is not worthy to belong to the profession and he certainly does not add to its reputation.

In conclusion, Mr. President and gentlemen, I wish to thank you all for the patient and kind manner in which you have received my address and more particularly because I feel that I have not been able to offer you anything which is new or original. I would also wish to express how great a pleasure it has been to me to meet so many of my distinguished and representative colleagues. We are all labouring in the cause of our noble profession and it becomes all of us to join hands and to assist and sympathise with one another, so as to advance our science and art and in this way increase our power for the cure and relief of humanity.

AN ANOMALOUS CASE OF CONTINUED FEVER WITH PERFORATIONS OF THE INTESTINE.



BY SIDNEY HERBERT SNELL, M.D., B.S. LOND.

With Note by Sir WILLIAM BROADBENT, M.D. Lond., *Post-mortem Report by* Dr. HUGH R. SMITH, *and Pathological Report by* Dr. E. D. W. GREIG.

THE patient was a man, aged forty-five years, a brewer, who had always been of quiet and temperate habits, living a plain semi-country life. He was of somewhat nervous temperament, with an occasional tendency to dyspepsia. He had not left home for over two months or eaten oysters. The illness commenced about April 20th, 1898, though it appears that he had not been feeling quite well for some weeks previously. On the 29th he was driving for some time in heavy rain, but does not seem to have been really wetted; however, that night he had a sharp attack of diarrhœa. I saw him on Sunday, May 1st, and noticed that he had a very yellow, "livery" appearance. On the 2nd I was requested to see him professionally. He then complained of a feeling of general malaise with slight headache; the "livery" appearance of the face had increased, but there was no actual jaundice and no fever. The tongue was coated with a white fur; the urine was normal. The bowels were acting once daily, the motion (the patient's description) was of a somewhat light colour with a little slime. Apparently the patient had some simple congestion of the liver. The symptoms continued without relief and on the 4th there was a little pyrexia. On the 5th the pyrexia had increased and the patient was placed in bed. On the 6th the temperature was 102·5° F. in the morning and 102·8° in the evening. There was still the same yellowish appearance but no jaundice. The bowels were open every day; the motions

Digitized by Google

were slate-coloured and semi-formed, with some mucus and occasional streaks of blood, but these last were obviously from hæmorrhoids, and the patient told me that they were often present when he was in good health. On the 7th the temperature was 103·6° in the morning and thereafter the temperature was recorded regularly every four hours. The patient was now treated as for typhoid fever. The high temperature fell rapidly until it reached normal on the 10th; it then again rose and continued vacillating between 99° and 101°, the highest temperature being usually recorded about 4 P.M. and the lowest at 4 or 8 A.M., but no great regularity was present. The patient's tongue remained thickly coated with whitish fur and was at times very dry. The pulse was slow, varying from 64 to 80; these variations seemed to occur for no particular reason. In ordinary health this patient's pulse was usually about 65. At this period of the illness, of course, I was in the greatest perplexity as to the nature of the complaint. The possibility of typhoid fever occurred to me almost from the first, but apart from the continued elevation of the temperature there was not a single sign or symptom of typhoid fever. At times there was a little headache and anon some fleeting abdominal pains due to flatulence. The bowels continued acting daily, but about this time the motions assumed a somewhat chocolate-coloured tinge. On the 16th, with Dr. H. R. Smith, I tried Widal's serum reaction with negative results, the movements of the bacillus typhosus being absolutely unaffected by the introduction of serum from the patient. Nevertheless, at this date he was seen by his brother-in-law, the late Mr. Iliffe, medical officer of health of Derby (whose sudden death occurred a very few days after), who had, of course, had great experience in typhoid fever, and he gave it as his opinion that, judging largely from the patient's facial expression, the complaint was typhoid fever. On the 19th a slight trace of albumin appeared in the urine. On the 20th I asked Sir William Broadbent to see the case in consultation. He pronounced the complaint not to be, in his opinion, typhoid fever, and particularly he regarded the motions as not in the least enteric in character. The tongue, however, had now a dry brownish colour with a triangular patch clearing up on the tip. From the 12th the patient had had 1 gr. of quinine every four hours and after the 20th 1 gr. of calomel in a pill nearly every night; this last just kept the bowels acting about once daily. During all this time the patient's general condition was good and the prognosis was apparently favourable, with an absolute want of symptoms or signs of any kind, save an occasional complaint from flatulence and some nervous irritability. From the 19th to the end of May the temperature varied only between very small limits, practically never exceeding 100° or falling below 99°. On the 23rd he developed a thrombosed hæmorrhoid, which we hoped might be the cause of the slight continued temperature. The thrombosed pile eventually sloughed off. A little pain and stiffness of the muscles of the neck and limbs occasionally were present during the latter part of the month. Towards the end of the month, too, there became perceptible the first sign that gave any real cause for anxiety—a sign which was the most remarkable one in this illness, and that was the gradually increasing frequency of the pulse. This, while maintaining its full, quickly collapsing character, showed an increase of frequency now varying between 90 and 100 and still exhibiting the characteristic of altering strangely in rapidity from time to time without apparent cause. There was no suspicion of dicrotism. On the 28th, therefore, digitalis was given (ten minims every 4 hours) and the amount of stimulant was increased to 6 oz. On June 1st there was mild diarrhœa for 24 hours, the bowels acting some six times, the motions being loose and yellow in colour—in fact, for the first time during the illness they became somewhat typhoidal in appearance. On this date the pulse was registered up to 120, yet the patient's general condition seemed fairly good and the mind was clear. Some emaciation was naturally now present, but it was by no means very marked; therefore, apart from the frequent pulse there seemed scarcely a grave symptom about him; but I laid considerable stress on the gravity of this sign in my prognosis to the friends. On June 3rd the sloughing hæmorrhoid separated and the midday temperature fell to normal. Save once, on May 30th, this was the first time it had touched normal since the fall on May 10th. For over twenty-four hours the temperature kept at or below normal; the patient was very weak but fairly cheerful and the outlook might have been hopeful save for the pulse, which kept varying between 90 and 110. On this day and night therefore the patient apparently presented the condition of being at the end of his attack of pyrexia, whatever it may have been, and, with the exception of the weakening heart, there were no morbid symptoms about him. How deceptive this short calm was became quickly apparent. On June 5th the patient began to show extreme weakness, while the pulse-rate leaped to 120 and a slight rise of temperature to about 100° again occurred. On deep pressure over the right iliac region there was now some distinct tenderness. On the 6th the mind began to wander for almost the first time during the illness, the pulse-rate increased to 130, still keeping its quickly collapsing character, and the patient's countenance assumed a very strikingly anxious and pinched appearance. The tenderness in the right iliac region was rather more marked, but the abdomen was not distended, not generally tender, and moved freely with respiration. At this stage Sir William Broadbent again saw the patient. From this time the pulse-rate rapidly increased and the patient very quickly passed into a pronounced typhoid condition and died on June 9th.

In the foregoing description of the course of this illness I have refrained from inserting negative facts; that the lungs were carefully examined, the spleen palpated, and the presence of any rash closely observed, readers will readily understand. Practically for the major portion of the attack the only sign of illness was a long-continued pyrexia hovering between 99° and 101°, with towards the end cardiac weakness, then death from heart failure. The report given below shows what was found at the post-mortem examination, which was possible in this case owing to the intelligence and common-sense of the relatives.

Note by Sir WILLIAM BROADBENT.—I saw this patient with Dr. Snell first on May 20th. There was nothing in his

Digitized by Google

appearance or facial expression at all suggestive of typhoid fever. The state of the tongue was the reverse of characteristic; the abdomen was normal in appearance and everywhere soft and supple; there was no enlargement of the spleen, but the liver could just be felt; no spots were or had been present. The motions, which had been kept for my inspection, were copious, heaped up, large-sized soft coils of a peculiar chocolate-brown colour, as unlike typhoid stools, therefore, as well could be. The temperature chart, again, was not that of enteric fever. Although, therefore, the investigation was begun under the idea that the continued fever of three weeks' duration without local cause was probably enteric, I came to the conclusion that this was not the case here. It seemed to me also that tubercle could be excluded, and the only diagnosis at which I could arrive was that there was intestinal sepsis of some kind, not specifically enteric or typhoid. On this hypothesis I recommended that a grain of calomel should be given daily for a few days. I was unable to modify my opinion at my second visit on June 7th, when, although the heart was evidently failing, the patient had not at all the appearance of a person dying from typhoid fever, nor were there any indications of perforation of the bowel when the abdomen was examined. It was consequently a great shock to me to receive a brief intimation that the cause of death was typhoid fever with perforating ulcers. Dr. Hugh Smith, however, added that the ulcerations were not of the usual character or in the usual situation, and this is shown by the excellent detailed description now given. The piece of intestine removed was afterwards brought to me for examination by Dr. Snell. I could find neither infiltrated Peyer's patches nor the elongated ulcers left when they have been destroyed by sloughing or ulceration. It is fortunate that bacteriological examination could come to the aid of clinical observation and morbid anatomy. There would otherwise have been no escape from the conclusion that typhoid fever could assume a type so aberrant as to be unrecognisable clinically, and could give rise to lesions quite unlike those usually met with in this disease. It would be premature to assume that the bacterium coli commune rendered specially virulent by unknown conditions was responsible for the train of symptoms and for the lesions met with in this patient, but it seems highly probable that such was the case. Further investigation will no doubt be made. I am reminded by this case of an opinion which I formed many years ago and to which, I think, I gave expression in my article on Enteric Fever in the first edition of Quain's "Dictionary of Medicine," that there was a disease called typhoid fever in India "which was not the enteric fever of this country." The late Dr. Wall, an old St. Mary's Hospital student, who gave his attention to this question at my suggestion, sent me clinical histories with post-mortem appearances which tended to confirm this opinion, but his early retirement from the Indian Medical Service put a stop to the inquiry. I still hear of anomalous instances of typhoid fever occurring in India which may be due to the specific bacillus, the effects of which are modified by climatic and other conditions or possibly may resemble the case related by Dr. Snell.

Report on post-mortem appearances by HUGH R. SMITH, M.D., M.R.C.P. Lond.—A necropsy was performed 20 hours after death. On opening the abdomen general purulent peritonitis was found which was evidently caused by three perforations in the small intestine between 12 in. and 16 in. above the cæcum. The peritoneal surface of the lower 3 ft. of the ileum presented several patches of intense injection corresponding in position with the ulcers subsequently discovered in the mucous membrane. The floor of these ulcers was very thin so that two more perforations were produced in the act of removing the intestines. Elsewhere the peritoneum presented no special features apart from the ordinary appearance of acute peritonitis. On opening the intestines the mucous membrane of the whole of the small bowel presented a normal appearance with the exception of the last 3 ft., where not only the mucous membrane but the entire wall of the gut was seen to be swollen, soft, and very pliable and in places in an almost necrotic condition; the lymphoid tissue was specially swollen, and the solitary follicles, particularly immediately above the ileo-cæcal valve, stood out very prominently. There were ten ulcers of the intestine, the first 3 ft. and the last 8 in. above the ileo-cæcal valve; they were irregular in outline and distribution, with fairly sharply-cut undermined edges and with smooth floors. In every case the necrotic process seemed to have involved the muscular layer, but in two or three the slough had not separated. The ulcers were not confined to Peyer's patches, although they seemed to start in the lymphoid tissue and tended to spread rather transversely than longitudinally. Five of the ulcers had perforated, but two of these were probably torn in removing the intestines. The mucous membrane in the neighbourhood of the ulcers was very swollen and friable and was slate-grey in colour. The mucous membrane of the large intestine was markedly swollen along its whole extent and was more friable than normal; there was no ulceration. The mesenteric glands in connexion with the diseased ileum were greatly swollen, but those in other parts of the abdomen were unaffected. The spleen was little if at all larger than normal. It felt soft, but was preserved entire for bacteriological examination. There was some collection of gas under the capsule of the spleen. The liver was fatty. The other abdominal organs were healthy. The heart showed very marked post-mortem staining and was soft and flabby and presented well-marked fatty degeneration of its walls. The other organs of the body were healthy. The brain was not examined.

Bacteriological report by E. D. W. GREIG, M.B. Edin.—The spleen, which was received 24 hours after death, was examined with the view of determining the nature of the organisms, if any, present. The spleen was placed in a sterile vessel and the capsule was sterilised by washing with absolute alcohol and then with hot sterilised distilled water. An incision was made into the spleen with a sterile knife. A number of stabs were made in different parts of the pulp exposed with a sterile platinum loop and with this a tube of ordinary peptone broth was inoculated. With a loopful of the juice of the spleen "successive" smears were made on agar plates. A portion of the pulp was removed with sterile scissors and placed in a tube of broth. The tubes of broth and the agar plates were placed in the incubator at 37° C. for one night. Next day they were examined. The plates showed a pure growth of round white colonies which were somewhat fluorescent. The broths were uniformly turbid and had a strong fæcal odour. A hanging-drop preparation made from the broths showed the presence of short bacilli which were slightly motile. Subcultures from the colonies on the plates and from the broths were made in all the media. The examination of the subcultures showed the organism to have the same characteristics in both the plate and the broth cultures. These characteristics were: (1) agar—was pure, and a microscopic preparation verified this and showed the presence of short bacilli with no filaments; (2) broth—was uniformly turbid but had a distinct scum on the surface; it had a very strong fæcal odour; at the end of three days the indol reaction was tested and found to be very marked; (3) glucose gelatin—a large amount of gas was produced; (4) milk—was coagulated in one night; and (5) potato—showed a fleshy yellow growth. From the broth culture a hanging-drop preparation was made at the end of twenty-four hours. It showed short bacilli very slightly motile. In other words, the organism gave all the reactions of the bacillus coli communis. Inoculation experiment.—A medium-sized guinea-pig received 0·5 c.c. of the broth subculture intraperitoneally. It died within twelve hours. Pure cultures of bacillus coli communis were obtained from the peritoneal cavity and spleen. This investigation shows that the bacillus coli communis was present in the spleen in a pure state. The inoculation experiment further shows that it was highly virulent.

Grays, Essex.

THE SOCIETY FOR PHYSICAL VOICE-TRAINING.—A meeting of this society was held on July 21st at London House, by kind permission of the Bishop of London. Bishop Barry presided, and made some strong remarks upon the importance of voice production. He thought the work was in very capable hands and had a fair prospect of success. Archdeacon Emery, the Rev. F. St. John Corbett, the Rev. R. Free, and others addressed the meeting and Mr. William Nicholl, the well-known singer and teacher, spoke of the necessity of balance between vocalisation and articulation. The report stated that lectures had been given in various parts of England, chiefly to the clergy, and at some of the training colleges.

FATAL CASE OF ACUTE POISONING BY LEAD CONTAINED IN DIACHYLON WHICH WAS TAKEN IN THE FORM OF PILLS FOR THE PURPOSE OF BRINGING ON A MISCARRIAGE.

BY GEORGE F. CROOKE, M.D. EDIN.,

FORMERLY PATHOLOGIST TO THE GENERAL HOSPITAL, BIRMINGHAM; PHYSICIAN FOR OUT-PATIENTS AND PATHOLOGIST TO THE QUEEN'S HOSPITAL, BIRMINGHAM; AND LECTURER ON PRACTICAL PATHOLOGY IN THE MEDICAL SCHOOL AT BIRMINGHAM.

As this case was the subject of an important inquiry held by Mr. E. Docker, coroner for North Worcestershire, at King's Norton on July 9th I have thought it worth while to send an account of it to THE LANCET.

I was called to the deceased, a young married woman, twenty-three years of age, shortly after midday on Monday, July 4th. When I arrived at the house I found her lying on the floor of the front room, raving in maniacal delirium, struggling violently with those who were endeavouring to restrain her, and apparently writhing in great agony. Her seizures were paroxysmal, her intelligence was quite gone, and she seemed to be unable to recognise anyone around her. It was evident at a glance that she was suffering from the effects of some intensely irritant poison and on making a remark to this effect the husband, who was present, informed me that he had every reason to suspect his wife had been taking "stuff" to bring on a miscarriage. At the same time he handed to me a piece of diachylon or emplastrum plumbi from which it was evident by the numerous facets that pieces had been cut off with a knife. I at once told him that in all probability his wife was now suffering from the effects of acute lead-poisoning. Her breath was fœtid and exceedingly offensive; the tongue was dry and coated with a greyish-black fur; blackened sordes had collected about the teeth and gums, along the free border of which there was a distinct slaty-blue line. After administering an injection hypodermically of morphia and atropia to relieve what seemed to be paroxysms of colic she was put to bed. The rectum was cleared out by an enema and a draught of chloral, bromide and iodide of potassium was administered. On account, however, of a peculiar spasm of the throat I was obliged to resort to small enemata containing potassium iodide, and sulphate of magnesia, with which some bromide and hyoscyamus were combined. The patient soon lapsed into a state of coma, on which convulsions of a violent nature supervened. She seemed to be blind and on examining the optic discs I found that both were quite choked. I tried to draw off some urine with the catheter, but succeeded in obtaining only a small quantity, just sufficient to test. This sample of urine was quite turbid, acid in reaction, contained albumin, and under the microscope leucocytes, a few red blood-cells, free epithelial cells, and a few cellular and hyaline casts. Thinking the convulsions might be uræmic and due to some suppression of urine I gave pilocarpine subcutaneously to bring on diaphoresis. Although the convulsions gradually diminished in regard to duration and intensity, yet in spite of all that could be done the patient gradually became weaker and sank from exhaustion on Wednesday, July 6th, during the night. From the time that coma and convulsions set in the temperature became considerably elevated, especially before death (105·4° F.); the breathing was very rapid, laboured and stertorous. The conjunctivæ were insensitive; the pupils at first contracted but afterwards dilated and she never thoroughly regained consciousness. During the attacks of eclampsia I noticed that the left arm was practically passive; it scarcely moved, but seemed paralysed.

The following is the history of the case prior to the fatal seizure. It appears that she had been taking the diachylon for some weeks, and on the Tuesday previous, June 28th, she had a miscarriage in the water-closet belonging to a neighbour's house. This was the second mishap during the last six months and it occurred probably about the third month of pregnancy. She would not lay up after it, but went about as usual as though nothing had happened. All this time she was looking wretchedly ill, complaining of intense headache, of abdominal pain, anorexia and thirst, of attacks of diarrhœa and vomiting, of numbness and loss of power in the left arm and hand, and of general weakness and prostration. Although neighbours advised and her husband begged of her to call in medical advice she obstinately refused to do so. It seems that, under the impression that there was something more to come away, she went on taking the diachylon after her miscarriage so that the lead had been gradually accumulating in her system until, as is sometimes known to be the case, its effects manifested themselves with remarkable suddenness and violence on the day I was called in to see her.

Necropsy.—According to instructions from the coroner I made a post-mortem examination on July 8th, about thirty hours after death, the results of which are as follow. The brain was quite soft in consistence, the membranes covering the surface (pia-arachnoid) looked opaque and thickened in places, the opacity and thickening being more or less patchy in its distribution. The blood-vessels in the pia mater—veins and capillaries—were much engorged and distended with blood and I came across several arteries which were plugged with thrombus, greyish-white in colour, so that in transverse sections the thrombi appeared as minute greyish points. Sections of a thrombosed artery made with the freezing microtome showed the thrombus to be composed of a fine fibrillated network of fibrin enclosing leucocytes and a few red blood-cells, similar in every respect to croupous exudation. The thrombus was firmly adherent to the vessel wall. The pia mater also presented numerous ecchymoses scattered in its matrix. The membrane was examined in the fresh state as follows. Small bits were stained in lithio-picrocarmine and then allowed to soak in changes of iodised serum. They were then treated with a ½ per cent. solution of perosmic acid and mounted on slides in iodised serum. From other pieces unstained fine sections, both horizontal and vertical, were made with the freezing microtome; these were stained in perosmic acid and mounted in Farrant's solution. Microscopic examination revealed some interesting changes. The walls of the smallest capillary blood-vessels were dotted over with numerous oil droplets and albuminoid granules darkly stained with the osmic acid, while the larger vessels showed adhering to their wall cells in a well-marked condition of granulo-fatty degeneration. These fatty cells corresponded either to the endothelium of the perivascular lymph-sheath or to the endothelium of the vessel wall. The muscle cells of the arterioles and small arteries were likewise fattily degenerated and, as seen in transverse or in longitudinal section, these latter vessels showed distinctly a considerably thickened wall. Another interesting feature was the irregularity in the lumen of some of the blood-vessels, which often ran a tortuous course. Here and there the lumen was quite dilated in a fusiform or globular shape and was distended with blood; in fact, quite aneurysmal in forms. Occasionally the perivascular lymph-sheath was found distended with red blood-cells and the extravasation was even extravascular. These blood extravasations into the fibrous matrix of the membrane were well demonstrated in successful transverse sections through an ecchymosed spot; and here, too, the connective tissue cells, as well as the flattened cells in the interfascicular lymph spaces of the lymph canalicular system, showed evidence of granulo-fatty metamorphosis, while other plasma cells contained granules of blood pigment. As regards the substance of the brain the cortex looked paler than usual, cloudy, and ill-defined, and there were scattered in its substance punctiform extravasations of blood. Microscopic examination showed pigmentary and fatty degeneration of the fusiform and pyramidal nerve cells as well as of the delicate neuroglia. As regards the basal ganglia—the corpus striatum and optic thalamus—there was nothing specially characteristic to note more than a general pallor and cloudiness of the grey matter, which seemed to have lost its lustre, so that the outlines of the nuclei were somewhat blurred and obscured. There was a greater quantity of fluid in the lateral ventricles, which seemed to be rather dilated. Still the changes just enumerated were too profound to be overlooked and they may explain to some extent the gravity of the cerebral symptoms owing to the disturbances in the nutrition of the brain for which these changes were responsible. I was not able to obtain portions of the nerve trunks supplying the left upper extremity for future examination as to evidences of neuritis.

With regard to the lungs, beyond œdema and hypostatic congestion of the bases there was nothing special to note. As to the heart, there was no enlargement, but the organ

Digitized by Google

was very soft and flabby and the left ventricular wall was quite lax and the cavity was somewhat dilated. The epicardium looked opaque and thickened in places and the endocardium and intima of the pulmonary artery and aorta showed a considerable degree of post-mortem staining. The muscle of the left ventricular wall was very soft and friable, of a pale reddish-brown colour, with slight yellowish and grey streaking. Under the microscope there was slight brown atrophy and also granular degeneration of the myocardium, while there was a distinct increase in the interstitial fibrous tissue. There were no valvular lesions. The liver was slightly enlarged, congested, and very soft and flaccid. On section the liver substance looked swollen, cloudy and opaque, and mottled with congestion and with shades of a greyish-brown colour. Sections examined under the microscope showed a slight degree of fatty infiltration of the peripheral zone, congestion and dilatation of the intercellular capillary spaces in the central zone of the lobules. The liver cells were swollen, much vacuolated, and likewise coarsely granular and fatty (osmic acid preparations). The stomach was empty, the gastric mucous membrane was coated with a gelatinous mucoid secretion, beneath there was both post-mortem staining and also ante-mortem congestion and ecchymosis; the rugæ were flattened. The mucous membrane of the intestinal canal was much congested in parts; the intestinal contents were a brownish liquid fæces in which mucous shreds and flocculi of mucus were mingled. The condition was that of gastro-enteritis. The spleen was enlarged, soft, and deeply congested. The kidneys were slightly enlarged; both were quite soft and flaccid. The capsules were slightly adherent in places. On section the medullary cones were purplish and deeply hyperæmic, the cortex looked swollen, of a pale brown or fawn colour, but variegated by a striated and punctiform congestion, and here and there showing a greyish yellow tint. Histological examination showed a well-marked parenchymatous nephritis. The tubuli contorti were blocked by swollen and granulo-fatty epithelial cells; in other tubules both in the cortex and medullary rays were found leucocytes and occasionally red blood cells, while others again contained here and there a hyaline or cellular cast. Another noticeable change was a general thickening of branches of the renal artery affecting the intima (endarteritis) as well as the muscularis and adventitia; the arterioles in the boundary layer also looked to be thickened. The fibrous capsule of the kidney was also irregularly thickened; there was thickening of the intertubular stroma. The uterus was enlarged to about the size of a large pear, the mucous membrane was thickened, soft and congested, and adhering to it were one or two coagula. It presented all the evidences of recent abortion, but otherwise the organ was quite healthy and nowhere either in its walls or around them was there the slightest evidence of inflammatory mischief.

Remarks.—My first acquaintance with mania as the result of lead-poisoning was made in Germany some fourteen years ago where I saw in an asylum at Dresden patients who had suffered from the effects of it. I met with other cases subsequently and only a year or two ago in the Potteries; and one of these cases is so similar in regard to symptoms and termination to this case that I will relate it. I was called to a middle-aged woman—an old and valued hand employed at one of the principal porcelain factories—who was said to have suddenly gone mad, after complaining a week or so of feeling unwell. I found her raving in a maniacal manner, struggling violently and held down by three or four women. There was an earthy pallor of the face, a well-marked blue line along the free border of the gums, offensive breath, furred and parched tongue, and as she had been working in lead in the glazing department I concluded that she was suffering from acute mania resulting from lead-poisoning. I obtained the assistance of a magistrate and the relieving officer, certified her, and she was removed straightway to the Stafford County Asylum, where she died, as I was informed, two days afterwards with much the same symptoms as the preceding patient.

In regard to the connexion of lead-poisoning with abortion I have heard of cases of miscarriage in women in the Potteries who became the victims of lead-poisoning. Some years ago the town of Sheffield was visited by an outbreak of lead-poisoning traced to the contamination of the water-supply, and I remember at the time it was noted that pregnant women who became affected either aborted or had a premature labour. I have reason to suspect that in this district the practice of taking diachylon in the form of pills to bring on miscarriage is far more prevalent among the working-class than is generally supposed. About eighteen months ago a patient came to me looking wretchedly ill, who admitted having taken diachylon for the purpose. After warning her of the serious consequences which might follow I prescribed for her, told her to go home and rest and call in medical aid if she became worse. From that day I saw no more of her. She miscarried, however, and afterwards became seriously ill and she was laid up for weeks with all the symptoms pointing to the poisonous action of lead—viz., gastro-enteritis and colic, maniacal delirium and slight epileptiform convulsions, intense headache with impairment of vision, and such prostration and weakness of the limbs, especially of the arms, that she feared she was going to lose the use of them. She was compelled to call in a medical man but refused to let them fetch me because I knew what she had been taking and "went on so to her about it." The medical man she did call in she tried to delude by ascribing her illness to a chill caught after miscarriage. And I have since been told of other cases where the victims of such folly have been ill for weeks after and have all but made a wreck of their lives. I have no doubt that not a few have been persuaded to take diachylon who would never have done so had they had any idea of its pernicious effects. I have heard of a case where a woman brought on not only miscarriage but following it also partial paralysis of an arm and hand, and this woman, after reading the account of the inquest, wisely exclaimed, "Never again." A friend of mine tells me of a case he saw in the out-patient room of one of the hospitals—a young woman with paralysis in one arm corresponding to the distribution of the ulnar nerve. She admitted having gone through a miscarriage a week or so previously. This is a case in which one may strongly suspect diachylon to have been the agent in effecting the miscarriage. In the light, then, of the present case I am sure the nature of some of the obscure nervous disorders, with the attendant anæmia, &c., in women who have admitted miscarriage—cases which now and then come under observation in the out-patient room—will be readily cleared up. During my tenure some years ago of the appointment of physician for out-patients to the Queen's Hospital in Birmingham I can call to mind such cases coming under my observation, the etiology of which was never satisfactorily explained simply by the fact of miscarriage. What may be the practical outcome of this case I must leave to the consideration of my readers. Diachylon is in almost every poor man's house; it is bought in the mass for the sake of cheapness and ostensibly for outward use only, though we know now to what terrible misuse its inward application has been put by some of the female community. It is, of course, generally used for cuts, sores, and spread on linen as plasters for drawing away the milk from the breasts after parturition. I regret that time and leisure have not given me the opportunity of looking up recent literature on the subject of lead-poisoning, but such as it stands and such as it came under my observation I have sent an account of this case in the hope that from a utilitarian point of view it may be considered worthy of being placed on record in THE LANCET.

Birmingham.

THE MEASUREMENT OF SUNSHINE AT OUR HEALTH RESORTS.

BY W. BLACK JONES, M.D., B.S. LOND.,
D.P.H. R.C.P.S. ENG.,
RESIDENT PHYSICIAN, LLANGAMMARCH WELLS SPA.

DURING the last few years a good deal has been written in the pages of THE LANCET in favour of those health resorts which enjoy a good daily record of sunshine. We have heard much of the value of open-air treatment in many morbid conditions which combines the advantages of a pure air with a maximum of sunlight. "Insolation" is a comparatively new word, meaning the exposure of any given thing to the influences of the light of the sun. The sun both breeds life and kills it. Its influence on the great natural processes concerned in plant life has long been established and that it possesses an influence for good on animal life is also known, but in this case the *rationale* of

Digitized by Google

the process is not so well defined. In plant life, at any rate, the subtle changes which are brought about are due probably exclusively to the actinic rays of the sun and not to the purely luminous rays. The actinic rays are the chemical rays of sunlight which bleach and exert a reducing action, as in its effects upon the sensitised silver plate. Is the action similar on the hæmoglobin which by alternate and complete reduction and oxidation favourably influences the condition of the blood? Sunlight has a well-known inhibitory effect upon the life of pathogenic organisms, and Koch has shown that direct sunlight kills the tubercle bacilli in a few hours and not infrequently in a few minutes. This action is not fully understood, but here again it is probably due to the actinic value of sunlight in effecting some marked chemical change. Those familiar with the ordinary processes of photography know full well how great are the differences between the effects upon a sensitised film of diffused light and direct sunlight. In other words, moisture as represented in the clouds cuts off much of the actinic power of unobstructed sunlight. It is the same in the effect upon organisms, for whereas, as just stated, direct sunlight kills tubercle bacilli in a few hours or minutes, yet they will live for five or seven days under the influence of diffused daylight or daylight filtered of its active chemical properties by the interposition of clouds. Everybody knows the exhilarating effect of a burst of sunshine in the spring after a dull period in the winter. This effect is probably due not to mere luminosity but to an increased actinic action, a chemical action the precise nature of which we cannot explain but which all the same is very generally felt in the form of invigoration and in taking "a brighter view of things." Indeed, the phrase "a brighter view of things" did we but know refers probably not to luminosity but to an increased activity engendered by the hidden and unquestionable benefits of pure unsophisticated sunshine.

The sunshine recorded at a given health resort, statistics of which of different places have appeared from time to time in the pages of THE LANCET, has hitherto related almost exclusively to its duration. The intensity of the heat may even be recorded, but the intensity of the light, especially in regard to its actinic value or chemical effects, has been hitherto ignored. To me this appears an important omission if we take as our postulate that it is the actinic rays of the sun, and not the luminous rays, which are responsible for biological action. It is certainly so in plant life and we may assume therefore that it is so in animal life. The duration of sunlight is admirably recorded by the Jordan's Recorder, but not for any practical purpose its intensity. Another sort of record may also be obtained by means of the burning effects of the sun, but this again is not an index of its chemical intensity.

At the meeting of the British Association held in Nottingham in 1893 Dr. S. Rideal communicated a very interesting paper on the Iodine Value of Sunlight in the High Alps. This seems to me to be a method depending essentially upon the actinic value of sunlight since a chemical change is produced and the amount of resulting products of the reaction may be easily estimated. The process depends upon the fact that sunlight liberates iodine from an acidulated solution of potassium iodide. The method is briefly as follows. A solution of potassium iodide is made up containing 20 grammes of the salt per litre. Likewise a solution of diluted sulphuric acid is prepared containing 11·9 grammes per litre of the pure acid. Lastly, 0·39 gramme of pure powdered arsenious acid is dissolved in a little water containing 1·5 gramme of potassium bicarbonate and then made up to a litre. In the following experiments 10 c.c. of the potassium iodide solution, together with 10 c.c. of the dilute sulphuric acid, were placed in a stoppered bottle of 50 c.c. capacity and placed upon a white porcelain plate and exposed to the action of the light. At the end of an hour the bottle is removed and bicarbonate of soda added in sufficient quantity to neutralise the free acid present. The bottle is next placed under a burette containing the arsenic solution. The latter is then run in until the colour of the iodine is completely discharged. I have employed this process (which is a slight modification of the method carried out by Dr. Rideal in the Engadine) at Llangammarch Wells, Central Wales, at different periods of the year and in some instances experiments were also conducted in London at the same time.

The following tables (I., II., and III.) are a synopsis of the results obtained at Llangammarch Wells of exposure of an acidified solution of potassium iodide to sunlight. The results are given in milligrammes of iodine liberated per 100 c.c. of solution used, each exposure beginning at about the hour named below and lasting for one hour. The Roman numerals indicate the hours. In practice 20 c.c. of the equally mixed solutions were used and by multiplying by 5 the results are recorded per 100 c.c.

TABLE I.—*Results of all Observations—i.e., Bright Sun, Medium and Cloudy.*

Hour	IX.	X.	XI.	XII.	I.	II.	III.	IV.
Number of observations	10	9	7	4	8	7	4	4
Mean number of milligrammes of iodine liberated	13·0	12·0	13·9	15·0	10·3	14·0	13·3	10·0

TABLE II.—*Results of Observations when the Sun was Shining Brightly for One Hour.*

Hour	IX.	X.	XI.	XII.	I.	II.	III.	IV.
Number of observations	4	1	3	1	2	2	3	1
Mean number of milligrammes of iodine liberated	15·0	14·0	14·75	15·0	17·7	17·7	13·5	11·0

TABLE III.—*Result of Observations when the Sun was Completely Clouded for One Hour.*

Hour	IX.	X.	XI.	XII.	I.	II.	III.	IV.
Number of observations	1	2	0	0	2	2	0	1
Mean number of milligrammes of iodine liberated	4·0	10·7	—	—	8·12	9·25	—	3·0

These observations were made during the period between May 25th and June 15th, 1897, and were undertaken with the view of ascertaining the variations in one place due to uninterrupted sunlight, cloudy intervals, and an entirely dull day. Two important deductions follow from these interesting records. On a day when the sun was shining brightly and continuously the maximum chemical or actinic effect occurred between one and two o'clock. In the case when the sun was completely clouded the results at the same time of the day showed about one-half of this chemical activity. The information gained in these experiments led me next to try the differences between the sunlight at Llangammarch Wells and at London on the same days. The results were as follows:—

TABLE IV.—*The Sunlight of London compared with that of Llangammarch (Summer).*

Date.	Hour.	Milligrammes of iodine liberated per 100 c.c.		Weather observations.	
		London.	Llangammarch.	London.	Llangammarch.
Sept. 10th, 1897.	IX.	—	12·25	—	Bright, sunny.
	X.	—	11·50	—	Bright, with cloudy intervals.
	XI.	3·0	14·50	Alternate sun and cloud.	Alternate sun and cloud.
	XII.	5·5	14·75	Ditto.	Bright, sunny.
	I.	7·0	13·5	Sunny, with cloud.	Alternate sun and cloud.
	II.	5·0	11·25	Ditto.	Bright, with cloudy intervals.
	III.	4·0	8·05	All sun.	Occasionally bright sun; otherwise cloudy.

It will appear, therefore, that the conditions being the same the sunlight in London has nothing like the actinic power of the sunlight at Llangammarch Wells, and probably at other places situated under a similarly pure environment.

Digitized by Google

The transparency of the air is, of course, the most important factor to be taken into account. In London the air is seldom transparent in the same sense that the air in the country or in Wales is transparent. Llangammarch in particular is situated in a charming part of the country and is sheltered from adverse winds amongst mountain scenery and is very remote from manufacturing centres. On the other hand, London is hemmed in by factories and other places which load the air with dust or smoke, which have a great effect in absorbing the actinic power of the sun's rays. It happened in London within a fortnight of these experiments to be foggy. The first fog, indeed, of the autumn of 1897 occurred on Sept. 27th. The fog was low-lying and the sun could be seen shining through the gloom. A bottle containing 20 c.c. of acidified potassium iodide was exposed from 11 A.M. to 5 P.M., that is, just six hours, with the result that the iodine liberated per 100 c.c. was only 0·5 milligramme or 0·08 milligramme per hour. This is a striking instance of the remarkable effect which fog has of absorbing practically all the actinic rays although light rays still penetrate.

The next experiments were conducted in the winter and fortunately again I was able to carry out similar experiments in Llangammarch and at the same time in London. The results over four days were as follows :—

TABLE V.—*The Sunlight of London Compared with that of Llangammarch (Winter).*

Date.	Hour beginning.	Milligrammes of iodine liberated per 100 c.c.		Weather observations.	
		London.	Llangammarch.	London.	Llangammarch.
Feb. 14th, 1898.	XI.	3·5	8·5	Sunshine, hazy.	Bright sun at intervals.
	XII.	5·0	7·5	Sunshine, bright.	—
	I.	5·0	9·0	,,	—
	II.	2·5	8·0	,,	—
Feb. 15th, 1898.	XI.	1·0	4·0	Dull; cloudy all day.	Fine rain all day.
	XII.	2·5	3·0	—	—
	I.	1·0	2·5	—	—
	II.	1·0	2·0	—	—
Feb. 16th, 1898.	XI.	5·0	2·5	Bright sun.	Cloudy all day.
	XII.	4·5	3·0	,,	—
	I.	6·0	2·0	,,	—
	II.	4·0	2·0	,,	—
Feb. 17th, 1898.	IX.	—	5·0	Dull; cloudy and dark.	Sun at first, then rain.
	X.	0·5	4·75	—	—
	XI.	0·5	2·0	—	—

Here also will be remembered the great superiority of the sunlight at Llangammarch in winter time when the conditions were meteorologically the same. Thus the maximum amount of iodine liberated in one experiment at Llangammarch was 9 milligrammes, whilst the maximum in London under the same conditions was 6 milligrammes. In both cases it will be observed that the maximum occurred at the same time between the hours of 1 and 2 o'clock. When it was cloudy all day at Llangammarch the activity of the light was always more than twice that in London under the same conditions.

I have already referred to Dr. Rideal's experiments on the iodine value of sunlight in the high Alps. His results were contained in the British Association Reports, 1893, at Nottingham, and 1894 at Oxford. He found at St. Moritz that the average amount of iodine liberated was 9·34 milligrammes per 100 c.c. per hour. The maximum hour value was 13·5 milligrammes on Jan. 1st, 1893, and the lowest was 5·7 milligrammes on the 24th of the same month. In the Grindelwald the average was 8 milligrammes per hour. In 1893, from Dec. 6th to Feb. 28th, 1894, the maximum at St. Moritz was 14·52 milligrammes per hour, the lowest value on Dec. 9th was 3·53 milligrammes, and the average value for the period was 7·05 milligrammes.

I venture to think that these results are very instructive and interesting since they show that at any rate at Llangammarch, and doubtless at other home health resorts, the power and activity of the sun even in the winter is in no sense inferior to that which falls upon the health resort of very high altitudes like the Grindelwald at St. Moritz. After all, the effect of sunlight must be largely determined by the purity of the air and a measure of the actinic value of sunlight must therefore be to some extent a measure of atmospheric purity. The mountainous districts at home, though not of the scale abroad, are notorious for the crystal transparency and clearness of the air, and the experiments I have made at Llangammarch Wells have given results which are by no means disappointing, but which, on the contrary, show that as regards open-air treatment and exposure to a sunny air we may count upon certain of our health resorts at home as providing conditions of an equal value with those in certain places abroad. Some pertinent remarks of Professor von Ziemssen are quoted by Dr. Arthur Ransome in an article in THE LANCET of June 11th, 1898, especially in regard to the treatment of patients at high altitudes. Professor von Ziemssen concludes that the only advantages in favour of mountain climates are "the pure dry air, the slight wind in winter." He then points out the disadvantages of treatment at high altitudes. Marked atmospheric changes occur not infrequently (wind, rain, and snow) and are injurious to the patient. They make the acclimatisation of many patients difficult, and patients with high temperatures (especially those who do not reside in the sanatoria) may become decidedly worse. Other objections are the wearisome journey, with all its bad effects, the separation from the family, the comfortless conditions in severe illness and in case of death; further, the financial anxiety and the economy necessitated. All these have a bad effect upon the patient. When the advantages and disadvantages are compared the former are not so clear as to indicate the unconditional recommendation of treatment at high altitude. The long journey from England is frequently undertaken with great distress to the patient.

It seems to me that the medical profession in England have been somewhat behind their continental brethren in bringing forward the probable advantages of our own health resorts. The experiments I have here recorded appear to me to encourage the belief that, after all, we possess health resorts at home which show equal advantages in regard to purity of air and sunlight, and both these are admittedly important factors in the treatment of disease. I hope the publication of this paper will induce others to adopt this method and report the results at other places. Certainly the results obtained at this health resort (Llangammarch Wells), which, according to the indications of the method employed enjoys the purest of air and the maximum life-giving properties of the sun, are calculated to justify such a step.

Llangammarch Wells.

THE PREVENTION OF TUBERCULOSIS.

BY F. RUFENACHT WALTERS, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE NORTH LONDON CONSUMPTION HOSPITAL.

THE new society so auspiciously started in embryo on June 22nd at the meeting at Sir William Broadbent's residence will have many matters to attend to. I may perhaps be permitted here to refer to a few of them.

The spread of tuberculosis depends mainly on two factors: on constitutional deterioration largely due to lack of fresh air and on infection. It can therefore only be successfully combated by educating the public in hygienic methods. Houses are on the whole better drained than formerly, but it is by no means certain that they are better ventilated. Many shops are being reconstructed with absolute disregard for ventilation. Scarcely an office in London keeps its windows sufficiently open, even in summer, and no doubt largely because of the imperfect enforcement of the Smoke Acts. But for this, out-door restaurants might flourish in London as they do in Paris, Stockholm and Copenhagen. Even medical men often fail to appreciate the dangers of vitiated air and are deeply impressed with the risks of open windows in early phthisis. It is quite hopeless to prevent the spread of tuberculosis without at the same time improving our organisation for its treatment. Phthisis is curable by combined medical and hygienic

Digitized by Google

treatment provided this be applied early and persisted in. Hygienic treatment is almost impossible so long as the conditions of home life are unaltered; and yet the poorer phthisical patients are treated for many months as out-patients before being admitted for a short time to a special hospital, after which it is a matter of pure chance what becomes of them. No doubt this arises partly from insufficient beds, but proper training in open-air methods is impossible in most of our chest hospitals owing to their position, so that instead of largely increasing the hospital accommodation in towns it would be more sensible to organise a series of sanatoria in the country under medical supervision. Such sanatoria have a most important educational value; for with a resident medical man there is a good chance of directing the daily life of the patients into proper hygienic channels. The convalescent homes as at present managed cannot take the place of such sanatoria, although some of them might well be converted to such a purpose. A patient of mine who is now phthisical had severe pleurisy following influenza eighteen months ago, which was apparently the beginning of his illness. After this attack he went to a convalescent home and lodged in the same room with a freely expectorating phthisical patient. No special precautions were taken concerning the sputa, which were cleared away by the visitors themselves. Comment is needless.

It is still the custom in hospitals for disease of the chest to lodge the subjects of heart disease, chronic bronchitis, and early and late phthisis in the same ward. With proper care there is little danger of infection; but such mixture of cases renders the hygienic treatment of early phthisis impossible. Hospitals for phthisical patients should receive them only until they can be transferred to country sanatoria, where all early cases should be received under medical control. When convalescent these should be passed into country colonies, suitably arranged for an open-air life and still more or less under medical supervision. Advanced cases should go to special homes or refuges. By such an organisation there would be a good chance of recovery for early cases and the public would be protected. If at least two years are needed in Colorado or the Alps a few months cannot be sufficient in England.

In France there is an admirable organisation for the treatment of phthisical children, who are sent from a well-arranged dispensary in Paris to one of two country sanatoria, and go thence when convalescent to one of several agricultural colonies to learn a trade which keeps them healthy. In Germany there are over 20 country sanatoria for poor phthisical patients, mostly supported by the sickness and old age insurance companies, who find it cheaper to restore their insurers in an early stage than to give sick pay when they are no longer able to work. As I have already described the treatment in these sanatoria[1] I need only repeat that they constitute a most important means of preventing the spread of tuberculosis.

Welbeck-street, W.

TWO INTERESTING CASES OF OVARIOTOMY.[2]

BY H. MACNAUGHTON-JONES, M.D., F.R.C.S. IREL. & EDIN.

CASE 1. *Large malignant ovarian tumour and smaller anomalous ovarian tumour removed from a patient supposed to be pregnant; recovery.*—The patient was a woman, forty-two years of age, who had had five children. Her last labour occurred in September, 1894, and her last catamenial period was in April, 1897. She had been a widow since November, 1897. The last marital act took place in September, 1897. I learned that pregnancy was suspected and that an anomalous gestation was surmised. There had been occasional attacks of diarrhœa and some sickness for the past six months. I saw the patient on May 28th, 1898. I found her greatly emaciated and very weak. The abdomen presented the shape and character generally seen with ovarian cystoma. On examination I found the skin tightly stretched over a large solid mass of stony hardness; this was moveable and appeared to be lobulated, while a sulcus to the left side seemed to divide it from a second mass occupying the left inguinal region. I could disassociate the uterus from the tumour or tumours; the cervix was very hard and there was an associated movement of the uterus. I arrived at the conclusion that there were no products of conception and that the mass was ovarian, and Mr. Bland Sutton, who saw the tumour before operation and was present when I removed it, considered that it was malignant—a view which I shared with him. The tumour gave the idea of a hard multiple fibroma. I operated on May 31st. On opening the abdomen by an incision which had to extend from a short distance below the ensiform cartilage to the pubes a quantity of ascitic fluid escaped. The large mass was easily delivered and the thin pedicle secured. The second (left) tumour was then removed and the pedicle dealt with. The only complication (which was a serious one for some time) was a return of diarrhœa which was most difficult to control and made the administration of nourishment also difficult. However, the patient left the home one month after the operation greatly improved in health and is now at the seaside. How emaciated she was before operation may be judged from the fact that she weighed 6 st. 5 lb. before leaving.

Mr. J. H. Targett reports the specimen as "a large solid tumour of the ovary with a portion of the adjacent broad ligament. The tumour measures 9 in. by 6 in. by 5 in. and its outline is lobulated and coarsely nodular. The surface of the tumour is smooth and free from adhesions. On section it is white, mottled with yellow and grey areas, and near its outer pole there is a cavity of the size of a hen's egg due to degeneration of the growth. The tissue surrounding this cavity is blood-stained and evidently necrotic. Some small thin-walled cysts containing clear fluid project from the surface of the tumour. The pedicle measures 3 in. in breadth and the Fallopian tube and mesosalpinx are œdematous, but otherwise normal. Histologically the growth is a scirrhous carcinoma."

Mr. J. H. Targett reports: "The small tumour is solid, pyriform in shape, and measures 4 in. by 2½ in. It has a somewhat nodulated exterior. The cut surface shows a rounded gelatinous area in the broader end of the tumour. This area measures 2½ in. in diameter and is fairly well defined. The rest of the tumour is fibrous and traversed by large thin-walled vessels. The gelatinous area is not quite homogeneous in appearance, the peripheral zone being more gelatinous than the rest. The Fallopian tube and mesosalpinx are normal. Histologically the tumour very closely resembles the specimen recently exhibited at the Obstetrical Society of London and referred to a special committee."

[The tumour referred to by Mr. Targett as bearing a resemblance histologically to the smaller tumour removed from Case 1 is one a section of which was reported on by a special committee to the Obstetrical Society of London as an adeno-fibroma, and was removed by me with a large fibroma of the uterus.]

CASE 2. *Semi-solid ovarian tumour with ascites; ovariotomy after general peritonitis which was followed by universal adhesions; recovery.*—The patient, who was forty-six years of age, had had four children. Her last pregnancy occurred in 1894 and her last catamenial period was in 1895. With regard to her history I saw this case with Dr. Disney on May 13th, and he gave me these facts: "I was called to see the patient for the first time on April 21st. She was complaining of slight pains in the abdomen, and having for the past five months increased greatly in size believed that she was in labour. I found a tumour inclined towards the left side; there was no fluid then and the temperature was 99° F. During the day the pain increased and at 11 P.M. I found a considerable amount of swelling; the temperature was 102°. The next day there was evident general peritonitis and the temperature was 104°. On the 23rd she nearly collapsed. This critical state lasted about four days, the temperature ranging between 103° and 105°. There was absolute constipation between April 20th and May 1st despite many remedies. Then the bowels acted naturally. From April 27th there was gradual improvement and by May 1st the temperature was 101° and did not become normal till May 11th. There was a great amount of swelling, and pain on pressure all the time. She was out of bed for the first time on May 14th and was removed for operation on May 19th." I agreed with Dr. Disney that immediate operation was the

only means of saving her life. The patient was then suffering from occasional attacks of pain and was kept under the influence of morphia. She was in an extremely enfeebled condition, so much so that the question of removal had to be anxiously considered. On the 21st I operated. The patient was so feeble that she could not stand; she was greatly reduced and, further, a very rapid and feeble pulse made me anxious about the anæsthetic. This, however, as in the last case, was most admirably administered by Dr. R. T. Bakewell, to whom and to Mr. Sutton, who assisted me in the operation, I feel specially indebted. On opening the abdomen the parietal peritoneum was found completely adherent to the large cyst wall; this was so to its entire extent. The pedicle was completely twisted. This I carefully detached all round before using the trocar and when the cyst had collapsed the bowel was found in various places adherent in festoons to the posterior surface of its wall; in fact, considerable loops of intestine were attached and had to be carefully peeled off, the vessels, where necessary, being ligatured. When all bleeding was arrested I inserted a drainage-tube. This I removed on the fourth day and the patient went to the seaside on June 15th. The recent attack of severe general peritonitis, the universal adhesions, the very enfeebled state of the patient at the time of the operation, and the importance of rapid operation before these adhesions had become stronger are the principal points of interest. Had the operation been delayed its performance, in my opinion, would have been impossible.

The specimen Mr. Targett reports as "a multilocular ovarian cyst, consisting chiefly of one large loculus with imperfect septa. The whole specimen is of about the size of an adult head. The pedicle appears to have been twisted and the surface of the specimen was universally adherent. The mesosalpinx was completely adherent to the cyst wall; the Fallopian tube was normal. There is no evidence of malignant disease."

Harley-street, W.

A CASE OF DEATH UNDER CHLOROFORM, WITH REMARKS.

BY ALEXANDER WILSON, F.R.C.S. ENG.,
SENIOR ADMINISTRATOR OF ANÆSTHETICS, ROYAL INFIRMARY, MANCHESTER, ETC.

THE following unfortunate fatality belongs to that class of chloroform accidents in which the respirations continue after cessation of the pulse. As I have previously endeavoured to show,[1] the symptoms in these cases indicate that the primary lesion is a paralysis of the circulation, and the respiratory centre is affected as a secondary consequence and succumbs from simple anæmia. The first warning of danger is a change in the circulation, manifested by pallor and a feeble pulse. There is no gradual paralysis of the respiration but, on the contrary, a misleading increase in the frequency and depth of the respirations, followed by incoördinate respiratory efforts which gradually cease. The important and notable point is that effective respiration persists at a time when no pulse can be felt, and respiratory movements may be present when the circulation is damaged beyond recovery.

The patient, a boy, aged fifteen years, was being anæsthetised with chloroform preparatory to the removal of a necrosed metatarsal bone. I was not present at the commencement of the administration, being occupied in the adjoining operating theatre, but I saw the patient the moment dangerous symptoms supervened. Chloroform freely diluted with air was administered from a small square of folded lint. During the stage of excitement there was some struggling with holding of the breath, during which the lint was withdrawn from the face. Suddenly the patient began to breathe deeply and he became pale; the pupils were widely dilated and no pulse could be felt. The head was immediately lowered, the tongue was drawn out, and vigorous artificial respiration was begun. Called in from the next room, I found the boy lying on his back with the head and chest hanging over the side of the couch; the tongue was being held out with forceps and artificial respiration by compression of the chest was being employed. The cheeks and lips were of a good red colour, which returned slowly after pressure, but much more slowly than would have been the case had the rich colour been due to a vigorous circulation. The most dependent part of the forehead and the tips of the ears were just beginning to show a faint dusky hue. The pupils were of medium size, if anything a little contracted; there was no corneal reflex in either eye and the eyeballs in tension were about normal. There was no trace of pulse in either the facial, temporal, or carotid arteries. The patient was taking deep gasping respirations at intervals of from four to five seconds, and air was freely entering the chest. This fact was made quite clear on suspending the artificial respiration. Vigorous compression of the chest was continued, the body was alternately laid flat and semi-inverted, hot sponges were applied to the cardiac region, the limbs were rapidly and tightly bandaged, a tight bandage with a pad was placed round the abdomen, and a copious warm enema of brandy-and-water was given, &c. The respirations from being full and free soon came at longer intervals and were more of a gasping nature, degenerating rapidly into mere incoördinate respiratory efforts and ultimately ceasing. The rosy colour of the cheeks, present in the semi-inverted position, almost entirely disappeared when the head was raised, to return again on the resumption of the dependent position, but each time to a less degree as the blood became more and more venous, until the aspect at length became corpse-like. The pupils were widely dilated and it was evident that the lad was quite dead. The post-mortem examination threw no light upon the causes which led to the fatal result.

This case illustrates the futility of trusting to any one isolated sign in estimating the effect of an anæsthetic. Thus any observer, judging solely from the general appearance of the patient, the evident vitality of the respiratory centre, the good colour of the cheeks, and the undilated pupils, would have concluded that there was no danger. Yet when viewed in conjunction with the absence of the pulse these very symptoms, in themselves favourable, become symptoms not only of the gravest import but actually signs of dissolution. The exaggerated respirations, accompanied with pallor and an imperceptible pulse, indicated a failure of the circulation so serious as to induce anæmia of the respiratory centre—a condition which only occurs in fatal hæmorrhage or fatal failure of the circulation from other causes. The red, apparently healthy hue of the cheeks, under ordinary circumstances an indication of vigorous circulation, in this case succeeding to the previous pallor on inversion of the patient and being present in a pulseless subject showed merely how absolute was the paralysis of the circulation. It proved that the blood-vessels had in effect become inert tubes, in which the blood, no longer propelled by the heart or restrained by the arterial tone, was under no influence save that of gravity, and free to flow to any part according to the position of the body.

In this case, as in others of the same type, there was no sign whatever of respiratory paralysis in the ordinary acceptation of the term. The respirations and respiratory movements persisted long after cessation of the pulse, until the respiratory centre succumbed from exhaustion, as it does in death from hæmorrhage or in any sudden failure of the circulation. Judging from the invariable effect of chloroform on the blood-pressure, the primary lesion was no doubt a paralysis of the vasomotor centre. The practical point is that in these cases the first warning of danger is exhibited by a change in the circulation, shown by pallor or lividity of the face and alterations in the pulse. If there have been no struggling and holding of the breath and the blood is well aerated the failure of the circulation will leave the face deadly pale. Should there have been struggling, &c., and defective aeration of the blood the face will become livid. The pulse, could it be carefully observed throughout, would at an early stage show some sign of the fall in blood-pressure. It first becomes soft and compressible and quick—"a running pulse"; then it suddenly collapses, the beats coming slower and irregularly trickling under the fingers like a very slow aortic pulse. I have repeatedly noticed this latter condition and by treating it have been able to ward off more serious danger. The respirations, as already pointed out, undergo marked modification in becoming suddenly accelerated, but only at a comparatively late stage when the mischief is often beyond repair. It cannot be too much insisted upon that as the

[1] The Mechanism of Death under Chloroform, THE LANCET, Nov. 17th, 1894, and Sept. 11th, 1897.

Digitized by Google

primary lesion is in the circulation to the circulation must we look for the first signs of danger and to the improvement of the circulation must treatment be directed. If the case is left until the stage of deep respiration is reached recovery is almost hopeless.

As regards treatment the indications are obvious, but the application of remedies is difficult. We are dependent upon the circulation for the conveyance of remedies to the various organs, and in these cases, as a rule, by the time the danger is noticed there is practically no circulation. Hence all remedies requiring conveying by the blood, such as hypodermic injections, rectal injections, &c., have very little chance of reaching the organs which they are expected to influence. The indications for treatment are to raise the blood-pressure and to stimulate the heart and supply it with blood upon which to contract, while at the same time the flow of blood to the nerve centres should be facilitated. This is best done by mechanical means, which in extreme cases are the only ones possible of efficient application. Thus artificial respiration by vigorous compression of the chest both raises the blood-pressure and stimulates the heart and is the only really useful remedy. Bandaging the limbs and compressing the abdomen help by limiting the area of the circulation. Transfusion if performed quickly might also be of some use. Dr. Leonard Hill has pointed out the influence of the position of the body on the heart, which treatment being easy of adoption is well worthy of trial.

As regards drugs, Professor Schäfer, Dr. H. L. Barnard, and Mr. F. Hobday[2] have recently drawn attention to the stimulating effect on the circulation of nicotine, extract of suprarenal capsules, hydrocyanic acid, and ammonia. All these possess the disadvantage that to be useful a fair degree of circulation must exist. Probably, from the mode and facility of administration, the most efficient will prove to be ammonia given by inhalations, as suggested by Dr. Barnard, and exhibited at an early stage before the respiration is altered or the circulation is completely paralysed. In my own experience I have found on several occasions in which the circulation showed the signs of failure previously mentioned that compression of the chest was enough to tide the patient over the danger.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF INTUSSUSCEPTION OF THE CÆCUM; REDUCTION AFTER LAPAROTOMY; RECOVERY.

(Under the care of Dr. F. G. PENROSE and Mr. T. H. KELLOCK.)

THE following very interesting case shows that under certain circumstances an intussusception may exist for three weeks and yet so few adhesions may have formed that the intussuscepted bowel may be withdrawn with comparative ease. The chief circumstance which renders such a thing possible is the fact that the large bowel is the portion of intestine mainly concerned as in this case. The interference with the circulation of the invaginated bowel was but slight and this was shown by the absence of blood from the stools and by the non-formation of peritoneal adhesions. The case is another confirmation of the advisability of performing laparotomy as soon as a patient comes under observation, for it cannot be doubted that in a short time the obstruction to the circulation of the intestine would have increased and it would have been impossible to release the bowel. Dr. Penrose and Mr. Kellock are to be congratulated on the successful termination of the case. For the notes of this case we are indebted to Dr. G. F. Still, medical registrar to the hospital.

A male child, aged sixteen months, was admitted to the Hospital for Sick Children, Great Ormond-street, on Feb. 9th, 1898, on account of pain in the abdomen. He was the youngest of three children; one of the others had died from enlarged head and spleen and the third was alive and well. There was a history of phthisis on both sides of the family. The patient was a full-term child, apparently quite healthy at birth; he was brought up on the breast alone until he was eleven months old, when he was given cow's milk, puddings, bread, &c. The bowels had always been regular, but the motions were sometimes slimy and offensive. He had had no serious illnesses but he had not appeared to thrive since the time when he was taken from the breast. In August, 1897, he was unconscious for a few minutes after a fall and in September he had discharge from both ears for three or four days. Three weeks before his admission to the hospital the mother noticed that the child had pain in the abdomen which came on suddenly, causing him to roll about and double himself up; this lasted for some hours, and since then these attacks of pain had occurred at least once a day and had been accompanied on three occasions by vomiting. The attack for which he was admitted had been more severe and had lasted longer than any of the previous ones, and during it he had vomited green fluid six times. There had been no blood noticed in the stools or any straining. On admission to the hospital the child was well nourished; he was strikingly apathetic and listless, even rectal examination failing to make him cry. The expression of the face was not at all suggestive of any serious abdominal condition; he lay quietly with the legs flexed on the abdomen, which was not distended or tender and moved well with respiration. In the left iliac fossa a sausage-shaped tumour was felt lying in the direction of the descending colon and reaching to just below the anterior superior spine of the ilium; the tumour was very hard and somewhat irregular in outline, the hardness varying during examination. A less defined tumour of the same shape could be traced as a continuation of this upwards to the left hypochondrium, across the epigastrium about two fingers' breadth above the umbilicus and curving downwards to the middle of the right lumbar region, where it was lost; the right iliac fossa appeared to be more empty than normal. The rectum was found to be partially filled with semi-solid fæcal matter; no tumour could be felt there, but a little blood came away on the examining finger. The heart and lungs were normal. The temperature was 99·8° F. and the pulse was 144. The child was noticed to assume the genu-pectoral position, to which he immediately returned if disturbed. On the evening of the day of admission, chloroform having been administered, the abdomen was opened by a 4-in. incision commencing 1 in. above the umbilicus. There was a little fluid in the peritoneal cavity but no peritonitis. The small intestines being kept from protruding by a flat sponge two fingers were introduced and the tumour was easily found lying on the left side. It was extremely hard and was evidently an intussusception which reached the descending colon. The greater part of it was easily reduced by the two fingers assisted by manipulation from the outside and without bringing the tumour out of the abdomen. It was found, however, that the last three inches or so could not be reduced in this way, so this part was brought out of the wound and reduction was effected with some difficulty, the walls of the gut being very thick and hard. The intussusception was found to be one of the cæcum into itself; the last part to be reduced was that which had formed the apex. The vermiform appendix had practically no mesentery; it was slightly swollen, as also were some lymphatic glands near its base. When once reduction was complete there was no tendency for the invagination to return. The bowel having been returned the abdominal wound was completely closed. The child bore the operation well and slept fairly after a small dose of morphia had been given hypodermically. The temperature on the following morning was 103·8°, but it fell steadily and was normal on the third day. Thirty-six hours after the operation the urine was found to be strongly ammoniacal and of a dark green colour; this condition, however, disappeared during the day and with this exception recovery was uninterrupted. For some days the œdematous cæcum could be felt as a hard tumour in the right iliac fossa, but it gradually became smaller and softer. The wound healed by first intention; the

[2] THE LANCET, Jan. 1st, 1898.

Digitized by Google

stitches were removed on Feb. 24th and the patient left the hospital convalescent on March 2nd. The child has been seen once or twice since his discharge and continues to be in perfect health.

Remarks by Dr. PENROSE.—It appeared from the examination that there could be but little doubt as to the nature of the tumour. As the history was perfectly definite that the infant had been ill for three weeks I thought it advisable to call in the aid of one of my surgical colleagues immediately. The apex of the cæcum as the starting point apparently of the invagination is certainly unusual.

Remarks by Mr. KELLOCK.—The points worthy of remark in the above case seem to be as follow: 1. The nature of the intussusception, which was of a somewhat rare variety. 2. The ease with which after three weeks' duration the greater part of the intussusception could be reduced and that too without bringing the bulk of the tumour outside the abdomen. This fact, together with the possibility in this case of preventing the protrusion of any small intestine, must have minimised the shock which is a necessary accompaniment of an operation of this kind on a young child. 3. The occurrence of carboluria thirty-six hours after the operation. No carbolic acid having been introduced into the abdomen the only possible source of the condition was the dressing applied to the wound, for which double cyanide gauze wrung out of a 1 in 40 carbolic acid solution was used; it was, however, very transitory and appeared to do the patient no harm.

BULAWAYO HOSPITAL.

A CASE OF ABSCESS OF THE LIVER; OPERATION; RECOVERY.

(Under the care of Dr. FRANK ARNOLD.)

THIS is a good example of a "tropical" abscess of the liver in which the connexion between the disease and an attack of dysentery was very close. The operation of transpleural hepatotomy was much simplified by the pleural and peritoneal adhesions which had formed.

A man, aged twenty-two years, was admitted into the Bulawayo Hospital on Jan. 19th suffering from a first attack of dysentery. He had resided for five months in Bulawayo, he had not been to any outlying district, and he had gone direct from England, staying for five weeks at Cape Town on the way. On Feb. 6th he was discharged from the hospital, relieved of, but not quite free from, dysentery. On the 18th he was readmitted to the hospital, his dysentery having become subacute. For about 7 or 8 days after admission his bowels were moderately loose, the number of motions varying from 1 to 10 in the 24 hours. There were no rigors and vomiting was absent except on the exhibition of quinine; night sweats were profuse and exhausting; the appetite even for liquid diet was small. The temperature on the night of admission was 99° F. It fell the next morning to 96°, but rose again the same night to 102°. For the next six days the temperature remained high, rising in the evening to between 102° and 103° and falling in the morning to not below 100°. On the morning of the seventh day after admission the temperature was normal but rose again the same evening to 101° and from this date onwards to the time of operation the difference between the morning and evening temperatures was well marked; at night records of from 102° to 103° were the rule and in the morning a subnormal reading was invariable. On the ninth day after admission pain diffused over the liver area was first complained of and continued up to the date of the operation. This was not severe; no appreciable enlargement of the liver could be made out. It may be noted that the appearance of this pain was synchronous with the change in the temperature curve—namely, the more marked difference between the morning and evening readings. The patient's condition now remained almost stationary up to about March 3rd, when the pain in the liver became more marked and examination of that organ showed that enlargement was now appreciable, the lower border extending in general to about 1½ in. below the costal margin. The whole liver area was tender and especially was this the case with a marked enlargement to the inner side of the gall-bladder. Into this especially tender part the needle of an exploring syringe was introduced with a negative result. After a day or two the local symptoms became less severe and the liver area receded. On the 10th pain in the right shoulder over the supra-spinous area of the scapula was first complained of. On the 18th the patient's general condition was very much worse, he had wasted considerably; his persistently high temperature, night sweats, increased pulse rate, and sallow tinge of skin, all pointed to the presence of pus under pressure with consequent septic absorption. Accordingly the liver was again carefully examined and it was found that the area had diminished, the lower edge being about ¾ in. below the costal margin and the part to the inner side of the gall-bladder being less prominent and less tender. However, in the eighth intercostal space in the mid-axillary line a tender area of about the size of a half-crown was noticed; there was no bulging here, the skin was not red or œdematous, and no dilated cutaneous veins could be seen. On the 19th the needle of an exploring syringe was inserted at this spot and at a depth of 1¼ in. pus of a creamy colour and thick consistency was reached. Microscopic examination of this pus showed nothing peculiar; no amœbæ could be seen. On March 21st Dr. R. T. Michell, surgeon to the British South Africa Company's Police, kindly gave chloroform. Resection in the usual way of 1¼ in. of the ninth right rib in the mid-axillary line was performed and on cutting through the remaining soft structures the finger could be passed into the pleural cavity upwards for about 1½ in. and at this height the edge of the lung fixed by adhesions could be felt. There was no indrawing of air into the pleural cavity. The diaphragm was next cut through and a space could be felt between the liver and the diaphragm, but the apposition of these was unusually close, and it seemed to be probable that the previously mentioned tenderness of the liver had been a localised peritonitis uniting that organ to the diaphragm. The patient's condition both before and during the operation was too serious to allow of either a prolonged manipulation or the division of the operation into two stages. It seemed reasonable to conclude that between the external skin and the liver there existed a small pleural and a small peritoneal sac shut off from the general cavities. After ascertaining that the abscess had been correctly localised by means of an exploring syringe the liver was freely incised and about 6 or 7 oz. of thick pus free from smell were evacuated; the thickness of liver substance cut through was about ¼ in. On passing the finger into the abscess cavity it was found to be situated in the lower part of the right lobe, single, spherical, non-loculated, and of about the size of a small orange. The cavity was douched out with a warm solution of boric acid and Condy's fluid, a large drainage-tube was inserted, and a wood-wool pad, &c., were applied; there was practically no hæmorrhage either during or after the operation.

For the first three days after the operation there was considerable pain over the liver area generally and especially in the neighbourhood of the wound; the evening temperature varied from 100° to 103°, the bowels were confined, but the pulse kept soft and regular. This pain was probably due to the stretching of adhesions caused by the shrinking of the liver and the obliterative localised peritonitis and pleurisy which the operation had set up. On the 24th an attempt to open the bowels by means of a glycerine suppository was made but without effect. The next morning 5 gr. of calomel were given and in the evening at 9 P.M. a glycerine enema was administered. The bowels then acted freely with abdominal pain at the time but great relief afterwards. The same night the patient, during the temporary absence of the sister, endeavoured to sit up in bed and fell back. After this fall he had considerable pain which yielded to morphia. The discharge next morning was more copious and tinged with blood. The pain continued during the 26th and on the morning of the 27th the dressings showed a considerable quantity of bile, and the bowels when moved by a glycerine enema in the evening yielded a clay-coloured motion of very firm consistence. With this appearance of bile in the dressings the pain became less severe. On the 28th there was no bile in the discharge and on the 29th a normal-coloured formed motion followed a glycerine enema. Up to April 8th, eighteen days after the operation, the bowels were moved every second day by glycerine enemata with a gradually decreasing after-pain in the abdomen, but on the 9th, after considerable premonitory pain, the bowels moved of their own accord and continued to act daily. Occasionally some tenesmus occurred and mucus was passed. The pain in the shoulder persisted for about 14 days after the operation; occasionally the pain was referred to the elbow and prevented even passive movements of the joint, which was apparently at other times

Digitized by Google

normal. The after-treatment of the case presented nothing of interest beyond that the dressings for a time showed typical "anchovy-paste" discharge. The patient left the hospital five and a half weeks after the operation in good health and free from any local trouble.

Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimen.—Dysmenorrhœa.—Ovariotomy.

A MEETING of this society was held on July 14th, the President, Dr. H. MACNAUGHTON-JONES, being in the chair.

Mr. F. BOWREMAN JESSETT exhibited a Double Pyosalpinx with broad ligament cyst removed by laparotomy.—In the discussion which ensued the following gentlemen took part: Dr. PURCELL, Dr. C. H. F. ROUTH, Dr. HEYWOOD SMITH, Mr. MAYO ROBSON, and the PRESIDENT.

Dr. HODGSON resumed the adjourned discussion on Dysmenorrhœa and said that they seemed to be agreed that there was such a thing as mechanical dysmenorrhœa and that it could be cured by mechanical means. He was glad to find that Dr. Bantock advocated the stem-pessary; he had found it useful in many cases. Sometimes when there was such a tendency to spasm as to cause the stem to be extruded he was in the habit of sewing it into the cervix, removing it in six weeks. He had seen no harm result from its use.—Dr. SNOW could not see any advantage of gradual dilatation over rapid dilatation under an anæsthetic, whilst the latter had several special advantages. If a patient subsequently married dysmenorrhœa was no doubt often improved after gradual dilatation as after other procedures, but in the case of virgins in how many cases was the improvement after gradual dilatation permanent? He believed the ring pessary often did good in these cases by putting the vaginal walls on the stretch and so relieving congestion by equalising the pelvic circulation.—Dr. BURLEIGH-ROBINSON agreed with the objection raised by Dr. Giles at the last meeting to the term "obstructive" as applied to mechanical dysmenorrhœa. The pain was due to congestion which was aggravated by the tension of the broad ligaments in cases of displacement. The veins were principally affected and tended to assume a varicose condition. To relieve this he had adopted the plan, described in a paper in 1892, of placing the patient on an inclined plane with the feet raised for several days before the period. In some cases he had obtained good results by advising that the patient should always sleep with the foot of the bed raised by means of blocks; this was continued for several months.—Dr. TRAVERS said that he had paid attention for many years to the question of dysmenorrhœa and had seen cases yield to Hewitt's treatment, to the Hodge pessary, and to various other kinds of vaginal pessary. He thought it would be a mistake if the opinion went forth that the society condemned all vaginal pessaries in the treatment of dysmenorrhœa. The stem pessary had also been useful in certain cases.—Dr. PURCELL remarked that there were some cases in which no local treatment or even examination was possible, especially in the case of some unmarried women, and then they must rely on medicinal means and measures of depletion. When local treatment was possible he thought gradual dilatation answered best.—The PRESIDENT urged that in every case a clear gynæcological and scientific differentiation of the cause of dysmenorrhœa should be aimed at, and whether the patient were young or old an examination should be made under an anæsthetic if necessary. He did not think "mechanical" was a scientific term and "spasmodic" was open to objection, for in all such cases some interstitial change was found in the uterus, or secondarily in the ovaries or tubes, and he believed there was no true analogy between these cases and organic or spasmodic stricture of the male urethra. Elevation by means of the inclined plane had been recommended by Dr. Heywood Smith many years ago, whilst raising the foot of the bed by blocks was suggested by Goodell of Philadelphia, who spoke of it as "putting the ovaries to sleep."—Dr. BANTOCK and Mr. SKENE KEITH briefly replied.

Dr. MACNAUGHTON-JONES read a paper, illustrated by specimens, on Two Unusually Interesting Cases of Ovariotomy, an account of which will be found on page 259.—Mr. BOWREMAN JESSETT and Dr. PURCELL briefly commented on the paper and Dr. MACNAUGHTON-JONES replied.

The Development of Ovariotomy.

A special meeting was held on July 23rd to hear Professor A. MARTIN'S address on the Development of Ovariotomy. The President, Dr. MACNAUGHTON-JONES, was in the chair, and there were also present: Professor Sanger (Leipsic), Dr. Theodore Landau (Berlin), Professor Mangiogalli (Milan), Dr. Howard Kelly (Baltimore), Professor Lapthorne Smith (Montreal), Professor Gardiner (Montreal), Dr. Young (Sydney), Professor Jacobs (Brussels), Sir James Dick, K.C.B., and Surgeon-General Jameson (the Director-General of the Royal Army Medical Corps).

Reviews and Notices of Books.

A System of Practical Medicine. By American Authors. Edited by ALFRED LEE LOOMIS, M.D., LL.D., late Professor of Pathology and Practical Medicine in the New York University, and WILLIAM GILMAN THOMPSON, M.D., Professor of Materia Medica, Therapeutics, and Clinical Medicine in the New York University. Vol. II.: Diseases of the Respiratory System, Diseases of the Circulatory System and the Mediastinum, Diseases of the Blood, Diseases of the Kidneys, Diseases of the Bladder and Prostate Gland. Vol. III.: Diseases of the Alimentary Canal, Diseases of the Peritoneum, Diseases of the Liver and Gall-bladder, Diseases of the Spleen, Diseases of the Pancreas, Diseases of the Thyroid Gland, Chronic Metal Poisoning, Alcoholism, Morphinism, &c. London: Henry Kimpton. 1898. Price 25*s.* per volume.

THESE two handsome volumes, the scope of which is fairly indicated by the contents of the title-pages cited above, were issued recently at intervals of three months, and there now only remains to appear a fourth volume which will complete a work of somewhat wider extent than the ordinary text-book, but less ambitious than some modern "Systems." The second volume opens with an article upon the Affections of the Nose and Larynx by Dr. Edwin Solly of Colorado. His experience at that famed health resort makes his testimony as to the proportionate frequency of tuberculous laryngitis of much value. He contrasts this with other returns and concludes that laryngeal complications occur in about 30 per cent. of the cases of pulmonary phthisis and laryngeal ulceration in about 13 per cent. Dr. Eldridge Cutler of Boston writes upon Physical Signs of Pulmonary Disease. His descriptions are concise and free from theoretical disquisitions. We were interested to observe his statement that a pulsating empyema may be differentiated from aneurysm not only by its locality, but also by the fact that the former may almost always be made to disappear by pressure and that it increases in size with increased expiration. Dr. Lawrence Mason writes on Bronchitis and Bronchiectasis, as well as on Asthma and Hay Fever. There is nothing special to note in these or in the other articles on pulmonary diseases for which Dr. Reginald Fitz and Dr. W. W. Gannett are responsible. They are hardly full enough for a work of this class. Dr. Herbert Witney describes the "Non-tubercular Diseases of the Pleura," wherein he includes the various forms of pleurisy, empyema, pneumo-thorax, echinococcus and malignant disease. Surely it is barely correct to use the general title, especially as in the text the relationship of sero-fibrinous pleurisy to tuberculosis is discussed with the result that at least 40 per cent. of the former are considered to be dependent on the latter condition. Amongst the several articles upon diseases of the heart we observe one on Endocarditis by one of the editors, Dr. Loomis,

Digitized by Google

whose death occurred just as the first volume was about to appear. The article is a concise description of the "simple," "malignant," and "fibrotic" forms and comprises an account of chronic valvular disease of which the section on prognosis is particularly worth noting. The articles of Dr. J. T. Whittaker on Neuroses of the Heart and on Diseases of the Blood-vessels constitute perhaps the most thoroughly worked-out articles in the volume. In his description of Arterio-sclerosis and also in his account of Thrombosis and Embolism and of Aneurysm Dr. Whittaker conveys a vast deal of information based on the most recent knowledge. There is a useful and practical account of the Examination of the Blood by Dr. F. C. Shattuck and Dr. R. C. Cabot preceding their accounts of the various diseases of the blood. They devote a separate section to a discussion of the significance of leucocytosis and make out a good case for the value of this condition as a means of differential diagnosis. Dr. Henry P. Loomis writes upon Diseases of the Kidneys, dividing nephritis into the two great groups of acute and chronic and using the affix "diffuse" to indicate that the lesions are distributed throughout both organs. He thus distinguishes the classes of acute diffuse nephritis, chronic diffuse parenchymatous nephritis, and chronic interstitial diffuse nephritis, and in diagrammatic form shows that the acute disease may, like the chronic parenchymatous, pass by way of the "large white kidney" into the "smooth cirrhotic" form, whilst the "chronic interstitial" is of two types, both of which are common—namely, the "genuine inflammatory cirrhotic kidney" and the "degenerative cirrhotic kidney," or arterio-sclerosis of the kidney. The article is illustrated by several good micro-photographs. Dr. I. N. Danforth writes on Renal Calculus and other conditions as well as upon Diseases of the Bladder and Prostate, whilst to Dr. T. D. Colman are assigned the subjects of Abnormalities of the Urine and Uræmia. He refers to the various views propounded upon uræmia and shows how much light has been thrown on the subject by Bouchard's researches, the conclusions of which are fully stated.

The third volume is in great measure devoted to the consideration of gastro-intestinal and hepatic diseases and the articles upon these subjects show very well to how great an extent these subjects have been studied of recent years. Dr. C. G. Stockton and Dr. Allen Jones describe the Diseases of the Stomach, devoting considerable space to the methods of examination of the viscus and of its contents. It is evident that the subject of dyspepsia has at length emerged from the somewhat vague and uncertain position which it used to hold and that modern science, with its new methods of observation, is fast advancing our knowledge of the conditions which underlie the functional derangements of the secretory and motor apparatus of this important organ. Whether these new methods have really done very much to diminish the trials of the sufferer from dyspepsia may perhaps be open to question. There are very good accounts of gastric ulcer, or "peptic ulcer" as it is termed, and of "dilatation of the stomach" and "gastroptosis," whilst the forms of gastritis are clearly differentiated. Dr. W. W. Johnston commences his account of Diseases of the Intestine by a description of ulcer of the duodenum and points out how its presence may be distinguished from gastric ulcer. His account of intestinal indigestion is of much interest and we would especially point out the full exposition given of the diagnosis of such a state from other and more grave conditions. Dr. Henry Lyman continues the subject of Intestinal Disorders by accounts of acute and chronic intestinal catarrh, of constipation, intussusception, and intestinal occlusion, the subject of Appendicitis being assigned to Dr. W. F. McNutt. This article is characterised by much common sense, the writer endeavouring—and not without success—to clearly differentiate the cases which may be safely treated by medical measures and those which demand surgical intervention. Articles on Intestinal Parasites and on Trichinosis are written by Dr. G. Dock, whilst the important subject of Food-poisoning (Bromatotoxismus) is dealt with by Dr. Victor C. Vaughan. In his contribution upon Diseases of the Liver Dr. J. E. Graham, after describing jaundice and functional derangements, &c., has a section upon Diseases in which the Hepatic Cell is Principally Affected, under which he includes phosphorus poisoning, syphilis, alcohol, toxins of infectious diseases, epidemic jaundice, acute yellow atrophy, food-poisoning, and Weil's disease. It may be remarked, however, that not much is known about the direct action on the hepatic cell of either syphilis or alcohol. The Hepatic Cirrhoses are subdivided into (1) vascular cirrhosis, comprising the toxic, infective, and dystrophic forms; (2) biliary cirrhosis, including hypertrophic and calculous cirrhosis; and (3) capsular cirrhosis, divided into localised and generalised perihepatitis. Dr. G. R. Lockwood writes on Diseases of the Spleen and Dr. C. G. Stockton on Diseases of the Pancreas, whilst the Diseases of the Thyroid are described by Dr. F. P. Kinnicutt who gives an excellent account of Exophthalmic Goitre. The subjects of Cretinism and Myxœdema are admirably treated by Dr. M. Allen Starr and are plentifully illustrated by photographs showing the effect of thyroid medication. The volume also contains articles on Alcoholism, Morphinism, Glanders, Anthrax, Rabies, Actinomycosis, and certain other subjects, such as Purpura, Hæmophilia, Filariasis, Diabetes, and Insolation. In conclusion we may remark that the work, as a whole, is one which well represents the science and art of medicine of to-day.

Practical Plant Physiology. By Dr. W. DETTMER. Translated from the Second German Edition by S. A. MOOR, M.A., F.L.S. Illustrated. London: Swan Sonnenschein and Co. 1898. Price 12*s*.

THERE is no truer remark than that of the translator of this book in his preface that the teaching of plant physiology has been seriously retarded by the want of suitable manuals of laboratory practice. In the study of botany, whether we are dealing with a theoretical or practical manual, the physiological portion of the work (which in practical works is often conspicuous by its absence) invariably consists of a somewhat condensed chapter or chapters forming a conclusion. We quite agree with the author that there is no need for an apology and congratulate him on having made his own addition to the meagre selection of English text-books on this subject. The book is divided into five sections, each of which is further divided into a suitable though varying number of divisions. We may consider one of these divisions—namely, that dealing with the movement of water in plants, leading up through transpiration phenomena to the much vexed question of the ascent of sap through the wood. In a series of experiments he shows the existence of root pressure, the influence of temperature on the flow of sap, the periodicity and causes of root pressure, the escape of liquid, several experiments on transpiration phenomena, and the movement of water through the wood. Two or three experiments illustrate each point, concluding with a few remarks as to the results, no theoretical questions being separately considered. From complicated experiments with the thermostat and on transpiration we pass to some delightfully simple illustrations. Thus on page 233 the following experiment is given. Twigs of *Tilia* and *Salix* are placed in separate narrow-mouthed bottles filled with water, the water being covered with oil. Both are weighed and re-weighed after a certain exposure to

Digitized by Google

diffused daylight. This determines the loss by transpiration; in either case the variation is noted and the experiment repeated in bright sunlight when a difference is observed due to the stomata, in the case of *Tilia* opening more fully in strong sunlight than in diffused daylight, those of *Salix* not being affected in this way. Such an experiment could be very well performed in the biological classes of our medical schools. The few lucid experiments by which the author shows that the ascent of sap takes place through the lumen of the wood vessel and not through the wood itself are also worthy of note. While as a whole the book appeals mainly to the research student it will be seen from the above instances that it would prove useful in the hands of a capable demonstrator in the biological classes.

The Mental Affections of Children—Idiocy, Imbecility, and Insanity. By WILLIAM W. IRELAND, M.D. Edin. London: J. & A. Churchill. Edinburgh: James Thin. 1898. Pp. 435. Price 14*s*.

DR. IRELAND'S former work on Idiocy and Imbecility was in its time the best English work on the subject and the present treatise will be welcomed by all interested in the subject. Some chapters are reintroduced with necessary modifications from the older work, but a great part is entirely new. Dr. Ireland commences with a general discussion of the causation of idiocy, in which he gives the chief place to neurotic heredity, considering alcoholism a less important factor *per se* than is generally held. He strongly combats the view that idiocy is to be looked on as an example of reversion to a lower type in the evolutionary scale. Dr. Ireland makes the following classification based on pathological grounds: (1) Genetous idiots, including the well-known "Mongolian" group; (2) microcephalic; (3) hydrocephalic; (4) eclampsic; (5) epileptic (6) paralytic; (7) traumatic; (8) inflammatory; (9) sclerotic (10) syphilitic; (11) cretins; and (12) idiots by deprivation. This classification is convenient, notwithstanding that from the point of view of symptoms the groups are much less definite. The fullest descriptions are of the genetous idiots and of the microcephalic. The general peculiarities of feature and of physical and mental development are very clearly given, although Dr. Ireland has been rather sparing in illustrating his descriptions from photographs of his cases. Individual and striking cases are described in detail, and there are some useful though rather brief accounts of the conditions of the nervous system found after death. Medical treatment in these cases calls for little remark, and Dr. Ireland has no belief in surgery for relieving the mental condition. Craniectomy, he believes—and we agree with him—to be useless for the relief of microcephaly, the operative procedure being "founded on an incorrect pathology." The chapter on Cretinism is a little disappointing. There is an admirable chapter on a subject which usually is passed over—Insanity in Children and Insane Idiots. The sensory deficiencies of idiots are described, but no mention is made of the excessive development of the powers of smell which has been recorded by others. The mental limitations of idiots and the best methods of educating them are described and a short account is given of the laws bearing on the subject. The book concludes with an interesting chapter on "Wolf Boys"—boys who are found wild and are supposed to have been fostered by wild animals. When serving in the army in India Dr. Ireland had opportunities of inquiring almost at first hand into several supposed instances. He believes that some were impostors but that most were idiots who had been exposed by their parents in the woods. He quotes some delightful stories of boys, reminding one of Kipling's Jungle Book hero Mowgli, but it is clear that Dr. Ireland is sceptical as to the truth of most of them.

Dr. Ireland is so well known as an interesting writer that expectation as to the quality of the book was pitched high and was not disappointed. It is the best account we have of an extremely difficult subject and is worthy of the great reputation and long experience of the author.

LIBRARY TABLE.

Economics, Anæsthetics and Antiseptics in the Practice of Midwifery. By HAYDN BROWN, L.R.C.P., L.R.C.S. Edin. London: J. & A. Churchill. 1897.—This is a clearly and sensibly written little book, which in the compass of 103 pages lays down some admirable rules for the conduct of a case of midwifery, including the interview with the patient for the purpose of fixing the expected day of delivery. Mr. Haydn Brown's remarks are eminently practical and cannot fail to be of advantage to the younger generation of practitioners.

Practical Organic Chemistry: the Detection and Properties of Some of the More Important Organic Compounds. By SAMUEL RIDEAL, D.Sc. Lond. Second edition. London: H. K. Lewis. 1898. Price 2*s*. 6*d*.—This is a compact little volume intended essentially for the student engaged in practical organic work. It contains no definite scheme for the identification of compounds, but it gives the specific reactions and tests for each body in separate paragraphs. The information is just such as will be a valuable help and guide to those preparing for the London University examinations. The present edition (second) is revised in accordance with the new Pharmacopœia. As the book is intended largely for medical students we think the section on urinary calculi should have been amplified. In regard to Pettenkofer's test for the biliary acids we have found the substitution of glucose in strong sulphuric acid to serve better than ordinary sugar, which the author recommends, since the former does not easily char and thus tend to obscure the colour reaction. Again, the "mirror" test for tartaric acid when tried in the way suggested does not always give satisfactory results. We prefer first to add potash to a solution of silver nitrate and then just dissolve the precipitate in the slightest excess of ammonia. If to this clear solution the dissolved substance suspected to contain tartaric or citric acid be added and the mixture gently warmed an excellent silvering of the tube results in the former case but not in the latter.

Les Troupes Coloniales: Hygiène du Soldat sous les Tropiques. (*The Colonial Troops: Hygiene of the Soldier in the Tropics.*) Par F. BUROT, Médecin principal de la Marine, Officier de la Légion d'Honneur, Officier d'Académie, Lauréat de l'Institut; et M. A. LEGRAND, Médecin de 1re classe de la Marine, Chevalier de la Légion d'Honneur, Lauréat de l'Institut. Paris: Librairie J. B. Baillière et Fils. 1898. Price 2 fr. 50 c.—This is a very useful and instructive volume in continuation of two preceding parts dealing with the causes of the diseases and deaths in the colonial army of France, which may be read with profit by medical officers and others interested in the hygiene of the French army. It deals in a lucid and logical way with a variety of subjects connected with the life of the French soldier abroad, the organisation and administration of the medical and sanitary services, and the special measures adapted for expeditions, the habitation, alimentation, and clothing of the soldier, the recruiting and selection of troops, the nature of the maladies to which soldiers serving abroad or on expeditions in tropical or sub-tropical climates are liable, with the hygienic measures of a general or special nature that either have been or are really required to be followed in order to avoid a large amount of preventable suffering and sacrifice of life as well as of public money. These are objects in which everybody is interested and an

Digitized by Google

incalculable amount of good would be done if the wise precepts and indications set forth in this volume were only carried out.

JOURNALS AND REVIEWS.

Tabib el Aila.—The Arabian medical writers are held in much repute historically, but in England, nowadays, there is seldom an opportunity of seeing contemporary sanitary works printed in Arabic. *Tabib el Aila*, however, a monthly sanitary journal published in Cairo, is now in the end of the third year of its existence, and has subscribers in countries as far apart as Syria and Morocco, but its chief circulation is in Egypt, where we are informed it is a well-known production of the native press. On the front (i.e., the right hand) page the Arabic title is accompanied by the French and English renderings, *Le Médecin chez Soi* and *The Doctor at Home*, which sufficiently indicate that the paper is intended for general readers. The June number consists of 24 pages (12 leaves) of about 20 lines each, to which are added 8 pages of advertisements. The opening article is a biography (with portrait) of Professor Potain, who is described in the Arabic text as having been born in Paris on July 10th, 1825. The subsequent papers are on the precautions to be observed by diabetics, the teeth, on clothing of phthisical patients, hygiene for females, prescriptions for diarrhœa and indigestion, deaths in the Spanish army in Cuba, letters from correspondents on various subjects, and notices of books. The proprietor and editor is Dr. Alfred Eïd of Cairo.

Annales de l'Institut Pasteur. Edited by M. E. DUCLAUX. Paris: Masson and Co. Vol. XII., No. 6. June, 1898.—This number commences with an important and well-illustrated article by Dr. Nowak of Cracow on the Histological Changes produced in Various Organs by Serpent Venom and by the Poison of Scorpions. Changes were chiefly found in the liver and kidneys and consisted of fatty degeneration and rapid necrosis of the hepatic cells and renal epithelium and some small, round-celled infiltration around the bile-ducts. The changes are similar to those found by Sanarelli in yellow fever and those occurring in the early stage of acute yellow atrophy of the liver. Dr. Nowak believes that the liver and spleen are affected because those organs are endeavouring to excrete the toxin. 2. M. Gabriel Bertrand has investigated the bio-chemical production of Sorbose, a peculiar sugar which was found first in a decoction of the berries of the mountain ash which was allowed to ferment spontaneously. M. Bertrand shows the production to be due to the action of a special bacillus and further shows that this bacillus is carried to the syrup by a particular red fly (Drosophila cellaris). Pure cultures of the bacillus will cause the production of sorbose in other liquids than rowan berry juice, such as a mixture of wine and vinegar, and even with cherry juice. 3. On the Maturation of Cheese, by M. J. Schirokich, dealing with the influence of diastase produced by the growth of species of tyrothrix. 4. On an Epidemic of Enteric Fever due to Tainted Water, by Dr. Schneider. 5. Report of the Pasteur Institute at Athens. 6. Critical Review on Proenzymes, by the editor.

The Journal of State Medicine. Vol. VI., No. 7. July, 1898. London: Baillière, Tindall, and Cox. Price 2*s.*—This number contains the conclusion of Professor Delépine's instructive paper on the Bacteriological Survey of Surface Water-supplies, in which he gives some interesting instances of the variations *quâ* bacteriological impurity in specimens of water obtained before and after heavy rainfall and when procured above or below a source of pollution. He also furnishes the results of some examinations showing the danger of relying upon filtration as a means of removing previous contamination. Hygiene in Plague forms the subjec of a paper by Captain W. O. Beveridge, R.A.M.C.; and a full account is given of the annual dinner of the institute.

Analytical Records
FROM
THE LANCET LABORATORY.

"AMIRAL" SOAP.

(THE AMIRAL SOAP SYNDICATE, 28A, BASINGHALL-STREET, E.C.)

"AMIRAL" soap is suggested as an external cure for corpulence and obesity. The idea is distinctly novel and is based apparently upon the solvent action upon fat of the active constituents of animal gall. The *rationale* of the treatment therefore is that when the soap is applied locally it is absorbed by the pores of the skin with the result, it is stated, of dispersing the adipose tissue. We confess to being sceptical as to the possibility of thus dissolving the panniculus adiposus, but we note that references are given of actual trials having been made with this result. It is stated that from two to four tablets of soap reduce the waist measurement of persons from three to five inches within one month. We found the composition of the soap to be well adapted for application to the skin. We could trace no injurious substances and it was quite neutral. It is a light green soap with pleasant aromatic smell. Further analysis showed that it contained a micaceous powder which when separated and placed between the fingers imparted a smooth slippery feeling like French chalk. On decomposing the soap with a mineral acid and filtering the separated fatty acids the clear filtrate was shaken with ether. On evaporating the ether a residue was obtained which gave a marked response to the tests for the biliary acids.

TABLOIDS OF ZINC OXIDE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUIDINGS, E.C.)

The tabloid of zinc oxide crumbles instantaneously when brought in contact with water. Each tabloid contains 2 gr. of the oxide. The ease with which this tabloid breaks up renders it well adapted for internal administration, as in the treatment of summer diarrhœa and gastralgia. In epilepsy resulting from peripheral irritation zinc oxide has been employed with encouraging results. The base has also been used for the relief of nervous tremors and in reducing the unsteadiness due to chronic alcoholism.

VALTINE MEAT GLOBULES.

(THE VALENTINE EXTRACT CO., LIMITED, ST. GEORGE'S HOUSE, EASTCHEAP, E.C.)

These preparations represent a new and valuable departure in meat extracts. Hitherto meat extract has been met with in the form of a dry paste or else in a nearly liquid condition. Both forms have their disadvantages. The valtine meat globules are made in various sizes and consist in reality of flexible capsules containing a definite amount of semi-solid extract of beef. No doubt some advantage is gained, especially in regard to flavour, from the fact that the concentration of the extract is not carried to a high point or near the solid condition. The result is that the contents of the valtine globule have a very fresh, agreeable, meaty flavour. Again, they are extremely handy and convenient to use, being made in sizes in accordance with various requirements. Thus to make a large cupful of beef-tea or clear soup of excellent flavour it is only necessary to place one of the large-size globules in hot water and to allow the contents to diffuse into the liquid. According to our analysis the extract possesses the properties of both a nutrient and stimulant. It was as follows: moisture, 26·21 per cent.; organic matter, 60·54 per cent.; mineral matter, 13·25 per cent. The organic matter contained nearly equal proportions of meat extractives (soluble in alcohol) and proteoses (insoluble in alcohol and precipitated by a saturated solution

Digitized by Google

of ammonium sulphate), with a trace of albumin. A further novelty, and one which we approve, consists in supplying with the globules tablets or "peloids" as they are called, containing various flavouring materials and condiments. Tastes differ widely as to the amount of condiment or flavouring which should be added to beef-tea or soup. By this device, however, each can satisfy himself. This step is particularly advantageous in the case of invalids who often find a meat extract repulsive on account of an objectionable added flavouring. Lastly, it should be stated that the valtine globules are made of a size to admit of swallowing whole without any difficulty. In this way nourishment can be readily administered where extract in the form of beef-tea or soup is unsuitable.

OREXIN TANNATE.

(KALLE AND CO., BIEBRICH-AM-RHEIN. A. AND M. ZIMMERMAN, 9 AND 10, ST. MARY-AT-HILL, E.C.)

Orexin tannate has been tried in the treatment of anorexia, as in phthisis, anæmia, and chlorosis, and in cases of atony of the stomach. It is a yellowish-white powder, not unlike calomel in appearance. It contains tannin in combination with "orexin," a base obtained by a synthetic process from certain coal-tar derivatives. It is soluble in dilute hydrochloric acid and probably therefore in the gastric juice. It dissolves also in alkali, according to our experiments, the solution turning a deep brown from the production of alkaline tannate. When the dry powder is heated in a tube it evolves a strong fishy odour characteristic of amines. Orexin tannate is said to be an excellent stomachic, stimulating the acid secretion of the stomach, encouraging its motor activity and materially shortening the process of digestion. The salt may be obtained in powdered form or in chocolate tablets, the latter containing 4 gr. of orexin tannate.

(1) "GAIACOPHOSPHAL" AND (2) "PHOSPHOTAL."

(SOCIÉTÉ CHIMIQUE DES USINES DU RHÔNE, 8, QUAI DE RETZ, LYONS. AGENTS: R. W. GREEFF AND CO., 20, EASTCHEAP.)

These interesting bodies are new combinations of guaiacol and creasote respectively, which are stated to present distinct advantages over the compounds hitherto used. "Gaiacophosphal" is a definite white crystalline salt smelling distinctly of guaiacol. On treatment with potash the smell of guaiacol is more strongly developed. The salt readily melts on heating, and speedily dissolves in water. "Phosphotal" is a phosphite of creasote and is a gummy looking liquid with a creasote-like smell. On warming with potash the guaiacol evidently separates. Experiments are quoted to show the advantages of these compounds in contrast with the phosphates and combinations hitherto employed. As is well known guaiacol and creasote have been administered with encouraging results in some cases in phthisis, typhoid fever, &c., and in respiratory disorders. These new salts are regarded as pharmacological improvements.

EFFICIENCY OR COMPULSION?

To the Editors of THE LANCET.

SIRS,—A report which I recently made to my committee on the relation of vaccination to the recent small-pox epidemic at Middlesbrough has been criticised by Mr. Alex. Paul in letters which he has written to various evening papers, and is also referred to in an annotation in THE LANCET of July 23rd. I take this opportunity of forwarding you a copy of this report, which to my mind points out as has rarely been shown before the value and protection afforded by vaccination; it also clearly shows where the weakness of the present system of vaccination lies—i.e., in the inefficiency of most primary vaccinations and the want of systematic revaccinations. The State requires its servants, the public vaccinators, to practise vaccination in a prescribed manner, but there is no such standard enforced in the cases of the numbers of children vaccinated by other medical practitioners who may and do exercise their own judgment as to whether they shall vaccinate a child in one, two, three, or more places. How many medical practitioners are there in this country who always perform vaccination with the efficiency required by the Local Government Board of the public vaccinators? And what medical man is there who at one time or another, when a mother has brought her child to him for vaccination and has pleaded for "just one place or two small ones, Doctor," out of the kindly sympathy of his heart has not yielded to this prayer in direct opposition to his better judgment?

Should not the Vaccination Bill now before Parliament have clearly defined what constitutes an efficient vaccination and the period for which such protection lasts and have made suitable provision for seeing that such a vaccination was performed in every case? Mr. Paul in his letters expresses astonishment that there should have been 1207 vaccinated persons attacked with small-pox at Middlesbrough, but how many of these 1207 can be considered to be really vaccinated persons—i.e., with scars of such an area and of such a quality as can be considered to be really protective and in whom the protection had not passed off through the lapse of time? We only know of 87 who had been re-vaccinated, leaving 1120 who had only had a primary vaccination. Of these 1044 were over the age of 15 years. If the 1120 were primarily vaccinated during the early months of infancy, as is very probable, then the 1044 cannot be classed as vaccinated persons protected from liability of attack, and the older they are the less is the protective or modifying value of the primary vaccination, this being most clearly shown in the table of deaths amongst the vaccinated class given in my report, the greatest mortality being at the greatest age periods.

The surprise at these results expressed by Mr. Paul denotes that he either looks at the question from the point of view of the biased anti-vaccinationists who do not care to examine both sides of the question or that he, like a great majority of the inhabitants of this country, is utterly ignorant as to what constitutes a thorough and efficient vaccination and what is claimed for it as a protection against small-pox. One fine day does not constitute a summer nor does a vaccination consisting of one or two small scars afford protection for life against liability to attack from small-pox. It should be our duty as medical men, together with all other believers in the virtues of vaccination, to instruct the population on these points and the former should see to it that every child submitted to them for vaccination should be so vaccinated as to ensure its being rendered immune to attack. If this were so the populace would soon gain confidence in vaccination and there would be little need to discuss the question of compulsion. The anti-vaccinationists would not be able to point to the fact, as they have done in the past, that the majority of small-pox cases occur amongst a so-called vaccinated community.

I am, Sirs, yours faithfully,

CHARLES V. DINGLE, M.D., B.Hy. Durh.,
Medical Officer of Health of Middlesbrough.

July 25th, 1898.

THE REPORT OF THE VACCINATION COMMISSION.

To the Editors of THE LANCET.

SIRS,—It is difficult to see what can be the object of the New Sydenham Society in simply reprinting the final report of the Vaccination Commission when it can be purchased of the Government printers at a very reasonable cost. But to print it without an index is still more inexplicable. It is a grave reflection upon *someone*—I do not know whether it may be the Commission itself or the Treasury—that it should have been left to General Phelps, the president of the Anti-Vaccination League, to publish an index to the report of the Commissioners as well as to that of Dr. Collins and Mr. Picton. These two indexes may be obtained (1*s.* each) on application to General Phelps, Edgbaston, Birmingham. They are very fairly done. As to an abstract of evidence, that is much more worth the attention and expenditure of the New Sydenham Society, but it will need to be carefully done to be really useful and by someone who is pretty familiar with the vaccination controversy. What is much more practicable and would be very useful and not very costly would be a consolidated index of the whole of the evidence. But that involves the Herculean labour of indexing the sixth volume, which, like the final report, was published without an index. It is understood that Lord Herschell has made an effort to get this latter defect remedied, but with what success I do not know.

I am, Sirs, yours faithfully,

Gloucester. FRANCIS T. BOND, M.D. Lond.

THE LANCET.

LONDON: SATURDAY, JULY 30, 1898.

ONE great value of periodical congresses such as that of the British Medical Association which is being held this week in Edinburgh is that they afford opportunity for the exposition of fresh facts and doctrines by men who can speak with authority, thereby adding to the general stock of knowledge and serving a very useful educational purpose. The Address in Medicine delivered by Professor T. R. FRASER certainly comes under this category, for it was mainly occupied with a remarkably lucid and exhaustive account of the present position of science in regard to the share taken by toxins in the production of disease and the new aspect which has been given to the interpretation of the facts of infective disease and the prospects which are offered for their mitigation and abolition. We cannot pretend to follow Professor FRASER in all parts of his scientific address; it must be read and read again before it can be fully mastered, but it yet behoves us to indicate what are its main teachings, since they have such important bearings upon the conception of the nature of such diseases and upon their treatment. It is undoubtedly true that toxic influences play a much larger share in the production of the phenomena of disease and of the structural changes which constitute morbid anatomy than could have been possibly conceived a few years ago. There is abundant evidence, direct and indirect, that poisoning, whether from without or within, plays a chief part in the derangements to which flesh is heir. Indeed, there would seem to be no limit to which this conception of toxæmia may not lead. It embraces conditions as remote from ordinary poisoning as it is possible to conceive, for who can say that auto-intoxication is not at the root of many a disorder, seeing how wide are the opportunities and how varied the conditions for the manufacture and the retention of substances within the body the action of which on blood and tissue is highly detrimental to their integrity. As Professor FRASER remarked, many of the ptomaines and leucomaines are alkaloidal in nature and rival the vegetable alkaloids in potency, and many a disease may well be ascribed to their agency. To some it would appear as if medicine were about to enter upon a new phase of generalisation, and they may see in the doctrine of toxins a parallel to some of the old speculations upon the nature of diseases.

The modern study of infective diseases offers ample scope for the application of this doctrine, only here we have to do with toxins produced by microbic agents which have been revealed by the labours of the bacteriologist. To explain the phenomena of an infective disease it is not merely necessary to postulate the existence of a pathogenic micro-organism, but it requires further that this microbe should produce a poison to which the symptoms and the morbid changes of the specific disease are due. That it is not the microbe that is the immediate cause of the phenomena is proved by the fact that the toxic effects are produced by the filtered solution of the material in which the microbes have been cultivated. Now one of the most remarkable facts about these infective diseases is the protection which a single attack generally affords against further infection. This fact, long observed in the diseases themselves, has been amply verified by experimental inoculations, but it has been still further advanced by the demonstration that the blood-serum of protected animals possesses the power of transmitting this resistance when injected into other animals. Professor FRASER showed that this acquired immunity could not be solely explained as we may explain the immunity to ordinary poisons by any theory of tolerance. Nor did he think it possible for phagocytosis to account for all the facts. He dwelt with necessary emphasis upon the singular differences in the duration of "artificial" immunity as compared with "natural" immunity, or that protection which an attack of the infective disease itself affords. He argued that in cases where immunity is prolonged there must be a continued reproduction of the protective substances, which implies the continued existence of the attenuated micro-organism which yields the antitoxin. This is a view which is most suggestive, and which seems to be necessary to explain the reason why the immunity conferred by antitoxic serum is so fleeting in comparison with the more permanent effect of an immunity conferred by the microbes themselves. We may well quote here a passage which conveys a moral to be taken to heart by all who are working at the experimental side of this question: "Unless by education we can so tame and civilise a pathogenic microbe as to subdue its virulent and hostile disposition while at the same time its beneficial and protective properties are left unimpaired, the hope of obtaining—as for plague, cholera, and tubercle—immunising vaccines equal in efficiency to the lymph of vaccinia will probably never be realised." And we note the warning that perchance the very germicidal action of glycerine which is being used to remove from vaccine lymph all external contamination may deprive the lymph of its long-lasting prophylactic power.

Professor FRASER discussed in some detail the origin of the antitoxins and antivenins and argued very plausibly that they are derived from the toxins and venins themselves, produced by chemical changes in the latter or forming part of their complex composition. If this be so it may, as he says, be only a matter of time before the resources of chemistry will enable us to extract the antidote from the poison, without recourse to the somewhat cumbrous method of serum production. He dwelt also upon the mode of action of antitoxins, which is still largely a matter of speculation; but if this is not yet clear it is at any rate accepted that in their employment the treatment of the diseases in which they are available comes to be that of a direct antidote, an attack on the cause of all the symptoms, an arrest of all the changes which are set up by the poison. His experiences with cobra venom have shown him how marvellously these mysterious antidotes act, and we cannot read his words without recognising that we

Digitized by Google

have within our reach remedial agents for diseases which have hitherto defied any direct treatment and for the mitigation of the symptoms of which we have hitherto had to rely mainly upon the *vis medicatrix naturæ*, aided by measures to sustain vitality and promote elimination. Already, however, in the partial way in which it has been possible yet to pursue it this line of treatment, in the guise of serum therapeutics, has effected much, and we join with Professor FRASER in the belief that a yet greater boon is in store for mankind, based on the recognition of the toxic origin of diseases and all that flows from that doctrine.

IT is open to question whether the custom of insisting upon an Address in Medicine and another in Surgery at the annual meetings of the British Medical Association would not sometimes be more honoured in the breach than in the observance. We fancy the distinguished surgeon to whom his brethren allotted the task of preparing an Address in Surgery at Edinburgh must have shared this view. For it is evident that he had nothing particular to say to the profession and his address is a plain, homely discourse on the present position of surgery. Many familiar topics are touched upon, none of them of any novelty, and upon none of them are his remarks of striking force or freshness. Mr. ANNANDALE playfully alluded to the necessity every Scotsman feels of dividing his discourse under certain "heads" and he chose the minimum—three. They were good ones, too, for he spoke of surgery in its scientific aspect, its practical aspect, and its moral aspect. Too much stress cannot be laid on the scientific basis of surgery. Science is a word which has come to be used in too technical and artificial a sense. We need to get back to its simple meaning—knowledge. We are too apt to think of it merely as a matter of test-tubes and microscopes, and so when the scientific aspect of surgery is discussed visions of bacteria rise in the mind. We would rather lay stress upon the importance of all branches of surgical knowledge and upon the fact that on all sides in every direction our knowledge of disease and of surgery has increased and become to a large extent defined. The days of empiricism are largely gone by, but we have not escaped altogether from the thraldom of tradition. The art of surgery—the handicraft—is a great accomplishment, but unless associated with a knowledge of nature's processes and powers its possession does not constitute a surgeon. Knowledge is power in everything, and only so far as we know health and disease, the causes, tendencies, signs, and consequences of morbid processes, can we deal with them with real success. The art of surgery is far in advance of the science; our failures arise far more from want of knowledge than from lack of skill. To the average man the acquisition of an art comes easier and is more attractive than the pursuit of knowledge and its results are more immediate. It is therefore all the more incumbent upon our teachers to lay the greatest stress upon the importance of knowledge and to show with unwearying iteration that it is by knowledge alone that we become truly fitted for the practice of our profession. There is one great department of surgery where the absence of this knowledge is almost complete and is attended with grave evil—we mean the pathology of new growths. Of the true nature of tumours we know practically nothing. An enormous amount of experience of their external features and "accidents" has been acquired, but we are as ignorant of their nature, their real cause, and their vital conditions as were our fathers. The result is that we are as powerless as they in their treatment and an empirical amputation is the only therapeutics we adopt.

There are one or two points in the moral aspect of surgery upon which, we think, Mr. ANNANDALE might well have enlarged. In our view the greatest of all the changes in the moral position of surgeons within recent times is the enormous responsibility which now attaches to a surgical operation. In former days the responsibility of the surgeon was limited to determining whether an operation should be undertaken and, if so, what and when. But now we have learnt that the issue of an operation is very largely under the surgeon's control and therefore a new burden is cast upon him. An operative failure cannot nowadays be disregarded as in the past and laid to the charge of fate or trust in Providence. It is not too much to say that this sense of enhanced personal responsibility should be ever present to the surgeon's mind, not as a haunting paralysing dread, but as a stimulus to be ever on the alert and at his very best. On the moral aspect of surgery, too, something may be said about the *cacoëthes secandi* that is not unknown in many branches of the art—the restless activity in the use of the knife that seems to regard the poor human frame chiefly as a field for operative displays. We have heard of surgeons who speak of operating as their "hobby," their chief pleasure in life, their one panacea against *ennui*. When the history of this century comes to be written the story of LISTER'S work will form a very bright page in it, but the historian will have to fill in the shadows if his picture is to be a true one, and to tell that the safety of a surgical operation led in some cases and in some hands to a reckless resort to operation.

IT is not surprising that the Vaccination Bill met with much criticism when reported last week to the House of Commons by the Grand Committee. The criticism, however, was devoted almost entirely to one point, with the result that an issue at least equal in importance was left entirely untouched. On the question of conscientious objection twenty-three speeches were made by Members of Parliament outside the Government and no less than twenty-one of these urged the Government to yield on this point and to make allowance for the alleged conscientious objector. It will be recollected that in the Committee Sir WILLIAM PRIESTLEY carried an amendment providing that, where a penalty had been imposed under Section 29 of the principal Act in the case of an infant no further penalty should be imposed until the child, had reached the age of four years, and even then that conscientious objection might be allowed for if the bench were "satisfied" of the genuineness of the objection. In the end Mr. BALFOUR, speaking for the Government, agreed to frame a similar clause with regard to infantile vaccination. This clause was carried, but in the course of the discussion it began to appear that many Members were now dissatisfied because the Government had yielded, and Mr. CHAPLIN pathetically complained that the

Digitized by Google

body of opinion in favour of the infliction of penalties had not given itself earlier expression. Ultimately when the question of the third reading came up protests that the Bill had been essentially altered were so numerous that the Speaker interposed and declared that in the circumstances the reading could not be taken.

That is how the matter stands at present. Many of those who argued for a conscience clause are heartily in favour of vaccination and all those who object to the same clause are equally anxious for the promotion of the Jennerian prophylaxis. There is simply between these parties a divergence of opinion as to the best legislative means for promoting vaccination. We have no hesitation in saying that if the Government had taken the advice which it has received from the medical profession it would have found itself in no such unfortunate position. In effect the advice has been that a provision recognising conscientious objection should be accompanied by a provision placing revaccination on the same footing as primary vaccination. That is the way, and the only right way, out of the present difficulty. As has been frequently shown in these columns since the Royal Commission issued its report there can be no hardship whatever in requiring vaccination at twelve years of age provided that allowance be made for persistent objectors. If Mr. CHAPLIN had been able to point out to those who now oppose the concessions which have been made that while he was relaxing the law with regard to infants this law, as relaxed, was now also to apply to adolescents, he would have closed their mouths so far as the promotion of vaccination is concerned. The application of the law to adolescents would so greatly increase the grand total of protection against small-pox in the country that the concession with regard to infants might have been gracefully yielded. Mr. CHAPLIN, however, has chosen to ignore revaccination and his punishment is that his Bill satisfies no one and that no one excepting the Government itself cares very much whether the measure is passed into law or dropped into limbo. Systematic revaccination could not, it it is true, be carried out without the aid of the Education Department, and it may be assumed as a rule that opposition is the natural attitude of a Government Department towards any proposal for the imposition of new duties and responsibilities. Quite likely the central educational authority has some vague fear that if school boards throughout the country were required to furnish to local authorities for vaccination periodical returns of children about to attain the age of twelve years the interests of education might in some degree be interfered with. Quite likely, too, this might really be the case if revaccination were to be made compulsory. But in the presence of a provision that any parent continuing to entertain serious objection to vaccination might by stating his objection to the bench be relieved of the necessity for submitting his boy or girl to vaccination there could be no hardship felt and no interference with education.

This was where the Royal Commission itself blundered. That body strongly approved of revaccination but did not find itself justified, in the state of opinion in some parts of the country, in recommending that revaccination should be made compulsory. There need, however, be no question of compulsion. Surely, the State, believing in vaccination and revaccination as the only practical means of preventing small-pox, has at least the right to demand that every parent in the country shall be at the trouble when his child is an infant and again when he or she attains the age of eleven or twelve years either to submit the child to vaccination or to go before a proper tribunal and declare his objection to the performance of the operation. From the beginning the Government has shirked this question and it owes its troubles in connexion with the Bill to its weakness on this essential point. If owing to pressure of other business it cannot now change the Bill in order to remedy its radical defects it would be far better to delay the whole subject for another year. The stated opponents of vaccination are dissatisfied. The supporters of vaccination are also dissatisfied. Every believer in vaccination, whatever be his opinion as to the relief of conscientious objection, believes also in revaccination. It can only be by providing for revaccination that the Government will gain any credit for its legislation and that small-pox will be kept in check in the adult as in the infant population.

Annotations.

"Ne quid nimis."

THE WATER-SUPPLY OF DORKING.

THE people of Dorking are suffering much from a deficiency in their water-supply. According, to a report now before us, at the last meeting of the Urban Council the chairman said that he had received many complaints from householders who had stated that they had been without water-supply for weeks. He had pointed out that in his opinion the council had no real power in the matter and that Parliament had given the "monopoly of the supply" to the water company, and that all he could do was to sympathise with those without water, which of course was of little use, but he thought the council ought to try to do something to provide water for the districts now without any supply. The clerk of the council had written to Lord Ashcombe, a neighbouring landlord, to ask him to allow the council to obtain water from a meadow in which there was a swimming bath and where there was an ample supply of water. If they could obtain water and send it round it might tide over the difficulty for the present. Unfortunately, Lord Ashcombe had not yet given permission that his water should be used for that purpose. The chairman thought that the town ought to acquire the Dorking waterworks. If the directors of the company were unable to get water possibly "the representatives of the people" might succeed in doing so. The immediate trouble, however, was to provide water for the emergency. The borough surveyor said that no complaint had been received with regard to the low service supply and he wished that people who had a proper cause of complaint would write so that a proper record could be kept. One member of the Council complained that he had been entirely without water and consequently had been unable to have a fire in his kitchen. If the water company had a monopoly of supply it was certainly their duty to supply the town. As a practical measure the chairman of the council then formally proposed that he should be authorised to make arrangements for the supply of the immediate necessities of the inhabitants who were without water, that additional labour should be employed for that purpose and that the water company should be informed that the council would hold

Digitized by Google

the water company responsible for the expenses incurred. One member of the council said that he had never had a constant supply of water although the water company was under a statutory obligation to give a constant supply if possible. The officials of the company had said that they could not give a constant supply, yet they extended the boundary of their area to include outlying places. He thought that the water company should be bought up. At the present time they were paying a dividend of 10 per cent. We give fully this report which has reached us. If correct it shows an extremely disgraceful state of things. According to the evidence the water company is a successful enterprise, paying no less than 10 per cent., and yet it does not carry out the work which it undertook under the privileges of a Parliamentary monopoly. The town council of Dorking have arrived at a very wise decision in agreeing to arrange as well as possible for the present supply of those people who are without water. We strongly advise all those who have suffered from a deficiency of supply to act on the suggestion of the borough surveyor and to note carefully the exact dates on which the supply was deficient. The town council would do wisely to at once communicate to the Local Government Board an accurate account of the state of things which at present exists in the borough. It need not be said that if the water company were at the present moment bought up by the town authorities they would be in no better position to supply the inhabitants than the company itself. Arrangements for water-supply take some time to carry out. Possibly the sources of the company are insufficient or they have not sufficient pumping power. The "municipalisation" of a company, it must be insisted on, does not increase either the amount of water in the wells or the efficiency of the pumping powers. If the Dorking Water Company does not carry out its statutory duties the town council of Dorking would do wisely to apply to Parliament for powers to enable them to carry out the supply for themselves. In a case of this sort it would be a monstrous injustice to the ratepayers for them to buy the company's works at an exorbitant price and then be put to the expense themselves of providing the water and the necessary pumping machinery. We heartily congratulate the town council of Dorking on the public spirit they are showing in doing the best they can in the trying circumstances under which they find themselves placed.

ARE TWO MEDICAL CERTIFICATES NECESSARY FOR LUNACY CASES?

THE Lunacy Act (1890) provides that two medical certificates are necessary in the case of patients—so-called "private cases"—who are removed directly to an asylum from their homes. On the other hand, for pauper cases who pass through the workhouse on their way to the asylum one medical certificate is sufficient, the reason probably being that during the patient's stay in the workhouse under a temporary detention order he is under closer observation. For the converse reason it is very desirable that the justice should seek in all cases sent *directly from home* the opinion and certificate of two medical men separately given, whatever the law may be. It is much safer that he should do so and fewer mistakes would happen, for in private cases it stands to reason that the medical man cannot know so much about the case when he only visits it occasionally and at chance times as when the patient is under the daily observation of skilled attendants and the medical officer of the workhouse. But, curiously enough, the justice is not bound to summon two medical men to his aid in every case "not a pauper." We have lately received a communication from one of our readers informing us that the lunacy justices of his district are in the habit of signing removal orders for lunatics of the working and artisan class on one medical certificate only, and asking if a lunatic can be so dealt with, he not being a pauper in receipt of medical or other parochial relief? The question raised is a very nice one and in order to settle the point a typical case with full detail should have been submitted. Further information is required and especially as to whether the patients in question pass through the workhouse or not on their way to the asylum. Let us first take the case of a patient who does pass through the workhouse and where the medical man certifying is the medical officer of that institution. It is not necessary that the patient should be in receipt of relief or be made a pauper for the justice to accept one certificate and summon one medical man to his aid. Section 18 of the Lunacy Act provides that the justice has to be satisfied that the lunatic is in such circumstances as to require relief for his proper care. "If the justice is so satisfied the lunatic shall be deemed to be a pauper" for the time being. He can then, by Section 16, act with one medical certificate only. Section 18 appears to give the justice discretionary power to consider the lunatic a pauper under certain conditions. That this is the correct reading of the Act is further supported by Section 20, which authorises a constable, relieving officer, or overseer to remove a lunatic to the workhouse, whether pauper or not; and the justice can act with one medical certificate, as in Form 8, which says nothing about the patient being a "pauper." In point of fact, a considerable proportion of London lunatics are removed to an asylum in this way—i.e., lunatics belonging to the middle- and lower middle-classes. They are not, and do not, thereby become paupers, but they pass *through the workhouse*, the one medical signatory being mostly the *medical officer of the workhouse*. Nevertheless, although the law stands thus in such cases, it is extremely desirable in the interests of the patient and of all concerned that two medical certificates should be obtained in cases which do *not* pass through the workhouse and where neither of the certifying medical men is the medical officer of that institution, as provided in Section 13. It is, indeed, a grave question whether such action as that mentioned by our correspondent is not distinctly illegal, for by Section 13 (2) unless the lunatic is a pauper or wandering at large two medical certificates are necessary. The point might well be laid before the Local Government Board either by a parochial medical officer or by the clerk to the guardians for decision. It rests with the medical superintendent of the asylum to which a lunatic is sent to refuse admission if the certification is irregular; and in such case the matter would probably be referred to the Lunacy Commissioners. Combined action of the medical practitioners of the district such as that contemplated is to be deprecated, at any rate, until the Local Government Board and the Lunacy Commissioners have been approached and a typical case has been laid before them.

QUID PRO QUO IN MONEY-LENDING.

THE generous money-lender is a person with whose kind offers of assistance probably every medical practitioner is familiar. His prodigal advertisements leave nothing to be desired. His purse is as full as it is free to the borrower. He asks for no proofs of solvency, for no security beyond a note of hand, and he abjures the inconvenient restraint of legal formalities. His delicate consideration is equal to his liberality, for he would have all communications guarded by the seal of privacy, third parties being entirely superfluous. Nothing could be more business-like than the celerity of his arrangements. There is but a promise on either side and the money flows over. All this no doubt looks excellent, but it has one fault. It is obviously ideal and unpractical. The demand is

Digitized by Google

not seen creating the supply but the supply creating the demand and ignoring risk—a pretty good sign that the wares and the market are not above suspicion. We are aware that medical practitioners no less than other persons are liable at times to an unavoidable tightening of means and that advances like those described above may naturally in such a case be expected to attract them. We may be excused for reminding them, however, that there are two sides to a loan as to every other bargain. The *quid pro quo* may be little spoken of, but it will be exacted nevertheless. The need of mutual guarantees and legal safeguards cannot, therefore, be dispensed with, however suave the lender's inducements. A prompt repayment may indeed remove all hazards, but where this can be relied upon the generous money-lender is not likely to be applied to. His offer is made rather to the unsecured poor man, by whom the promissory limit may easily be passed and with it goes the written guarantee for easy terms of interest and repayment. Young practitioners are especially liable to be snared by an offer of this kind and it is they to whom we would more particularly address a word of warning. Professional work of some sort can usually be obtained by one who is qualified to undertake it and the profits of such work, if not always large, are fairly reliable. They are at all times more worthy to be sought than the specious lure of a monetary loan by unknown persons with its millstone of prolonged and anxious responsibility. It is not required of the junior practitioner, however brilliant, that he should sacrifice every other good and even imperil his probity in order to purchase fame. A more moderate, even an obscurer, course will often bring him sooner to his goal. After all, there is no road to fame but through duty, and this latter does not consent to the reckless accumulation of debt. To live beholden to no one for the means of living is the best proof of that character which is essential to success; if in any case an advance is unavoidable it should certainly not be arranged on the unsteady basis of a money-lender's advertisement.

PLAGUE ON BOARD THE STEAMSHIP "CARTHAGE."

FOR a second time during the present plague prevalence in Bombay and Western India the disease has occurred on a ship bound for ports of this country. The case is that of the Peninsular and Oriental Company's steamer *Carthage*, on board which a coal-trimmer sickened with plague on July 6th. Two days later he was landed at Aden with the two members of the crew who had been told off to attend to him. But on the 14th—namely, six days after passing Aden—a second coal-trimmer was found to have slight symptoms of plague, and when the *Carthage* passed Malta the fact was announced by telegram to this country. The *Carthage* had intended to land passengers at Marseilles, but, doubtless, having regard to the panic which took place there in 1896–97 at the mere prospect of such an occurrence, the company decided that the vessel should come straight to this country, where it was certain that no panic measures would be taken. During the voyage and on the occurrence of both attacks the medical arrangements on board seem to have been excellent, the patients and their attendants being isolated in a large boat hung at a height above the side of the vessel in such a way as to avoid communication with others on the ship and at the same time to ensure every necessary comfort for the patients. On receiving the news from Malta the medical officer of the Local Government Board placed himself in communication both with the company and with the medical officers of health of Plymouth and the Port of London, and he found that the arrangements both on board and in these two excellently administered ports were such that no anxiety need be apprehended; and, as a matter of fact, the ordinary requirements of the Government order as to plague having been observed at both the English ports with which the *Carthage* communicated, passengers were allowed to land on giving their addresses. In the Port of London it was necessary to do little further than to isolate the second patient and his two attendants in the port hospital for a day or two so as to be quite certain that recovery and freedom from infection were complete. The *Carthage* was well appointed to deal with infection on board: she had a steam disinfector and ample appliances for disinfecting the localities occupied by the two plague patients, and her medical officer was fully conversant with the precautions which were necessary for the protection of the passengers and others. Indeed, the story of the *Carthage*, taken together with that of the vessels found two years ago to be infected on arrival in the port of London, goes fully to justify the opinion that, subject to due precautions at the port of departure and to proper administration on board ship, plague is a disease which may be easily checked on board a healthy and well-appointed ship at sea. Indeed, when account is taken of the great precautions which are always observed in the case of plague, we shall probably not be going too far when we say that on board such a ship as is now in question plague has less chances of spreading than would be the case if a passenger were attacked with scarlet fever or some other of our current infectious fevers. Great gain has also been achieved since the Venice Conference of 1897, for it is certain that before that date no ship in which plague had occurred between Bombay and Suez would have been allowed to pass through the Suez Canal merely after satisfying the local officials that all due precautions as to disinfection, &c., had been adopted. The case proves that the terms of the Venice Convention are ample to prevent the spread of the disease to European ports when cleanly and properly appointed vessels are in question, and it is only for such vessels that we in this country desire any leniency or any limit to the restrictions strictly demanded by medical and public health considerations.

BRITISH COLUMBIA MEDICAL REGISTER.

THE British Columbia Medical Register for the year 1898 is a pamphlet of 46 pages, printed at New Westminster by Messrs. Jackson and Co. Twenty pages are occupied with a Medical Act divided into 83 sections, a few of which, commencing with the opening paragraph, are as follows: "An Act respecting the profession of Medicine and Surgery. Her Majesty, by and with the advice and consent of the Legislative Assembly of the Province of British Columbia, enacts as follows: 1. This Act may be cited as the 'Medical Act, 1898.' 2. The members of the medical profession of British Columbia heretofore incorporated under the name of 'The Medical Council of British Columbia' shall be deemed to be and to have been from its first establishment a body corporate by the name aforesaid, and the said name is hereby changed to that of 'The College of Physicians and Surgeons of British Columbia.' ..... 3. Every person registered according to the provisions of the 'Medical Act' and any other Act of the Legislature of British Columbia relating to the medical profession shall be a member of the said 'College of Physicians and Surgeons of British Columbia.' 4. Every person hereafter registered under the provisions of this Act shall also be a member of the said College. ..... 24. ..... The Council shall admit upon the Register any person who shall produce from any college or school of medicine and surgery, requiring at least four years' course of study, a diploma of qualification ..... provided also that the applicant shall furnish to the Council satisfactory evidence of identification and pass before the

Digitized by Google

members thereof ..... a satisfactory examination touching his fitness and capacity to practise as a physician and surgeon. ..... 63. If any person not registered pursuant to this Act, for hire, gain, or hope of reward, practice or profess to practice medicine, surgery, or midwifery or advertise to give advice in medicine, surgery, or midwifery, he shall, upon summary conviction thereof before any Justice of the Peace, for any and every such offence pay a penalty not exceeding one hundred dollars." The typography of the Act and several subjoined pages is unfortunately disfigured by numerous misprints. There are 193 names of practitioners on the Register. Several examination papers are given which have presumably been already made use of, although the fact is not expressly stated. The one on chemistry does not present any considerable difficulties, whereas the one on theory and practice of medicine contains the following: "Give the microscopical appearances of the bacillus coli communis, the typhoid bacillus, the bacillus diphtheria (*sic*), the bacillus of leprosy, and that of syphilis."

THE PRINCE OF WALES.

As the accounts given in the daily press clearly indicate, the progress of His Royal Highness the Prince of Wales during the past week has been quite satisfactory to his surgeons. There have been no local complications and the general good health of the illustrious patient has been maintained. The extravasation in the joint has now almost completely subsided, and the small detached portion of patella and the ruptured tendon are effectively controlled by the apparatus. All the details necessary for his safe transport to the royal yacht *Osborne* in the Solent to-morrow (Saturday) have been carefully thought out and provided for and the fresh sea air and a change of scene cannot fail to be beneficial. His Royal Highness will travel in the train used by Her Majesty, and as it will reach Portsmouth at the proper time of tide there will be no hitch in the transference from the train to the yacht. In addition to Sir Francis Laking, both Sir William MacCormac and Mr. Fripp will accompany the Prince. The last-named gentleman will continue in attendance at Cowes, while Sir William MacCormac will go down from town to see His Royal Highness as often as may seem desirable.

HYSTERIA IN THE LOWER ANIMALS.

DR. H. HIGIER of Warsaw describes in the *Neurologisches Centralblatt* (No. 13, 1898) two instances of what he regards as hysteria occurring in the cat and the canary-bird respectively. The cat, which was nine months old, healthy and active, was one day deeply bitten in the back by a dog and immediately fell down paralysed. When Dr. Higier first saw it, five or six weeks after the injury, it walked only with its fore-paws, dragging its body and hind-paws. There was complete loss of sensation in the hind-paws and in the hinder third of the body, both sides of the abdomen and back of the animal being indifferent to deep punctures with a needle and to hot applications, but it always responded to gentle touching of the anterior half of the body. The tail was also paralysed, but there was no muscular atrophy of the hind limbs in comparison with the anterior part of the body, neither was there incontinence of urine or fæces, in which respect only did the symptoms differ from those of paraplegia intentionally induced by section of the spinal cord. Dr. Higier considered the lesion to be traumatic dorsal myelitis until one day the servant girl, being curious to see whether the cat would fall on all fours as cats usually do, threw it from the first-floor of the house on to the pavement. As a matter of fact, it alighted on all four feet, immediately ran away, and was, contrary to expectation, completely cured of its sensory-motor paraplegia which had lasted for more than two months. Dr. Higier based the diagnosis of hysteria on the sudden onset and equally sudden disappearance of the paralysis, together with the retention of control over the rectum and bladder. The mother of this cat had repeatedly during the last weeks of pregnancy suffered from general clonic convulsions without loss of consciousness (? chorea gravidarum). Dr. Higier's second case of hysteria showed itself in a canary-bird whose cage with the bird in it was pulled down from the wall by a cat, but Dr. Higier interposed before the cat seized it. The bird lay on the bottom of the cage, stiff as if dead, but was revived by sprinkling with cold water, after which it was lively, took its food well, and showed no abnormality except that from having been a fine singer it became silent. After six weeks this condition of aphonia passed off quite unexpectedly, and the canary once more sang very well. Dr. Higier also refers to three cases mentioned by Gilles de la Tourette in which dogs showed hysterical symptoms.

REMOVAL OF A BULLET FROM THE BODY OF THE AXIS AFTER ITS LOCALISATION BY SKIAGRAPHY.

IN the *Intercolonial Medical Journal of Australasia* Dr. F. Bird has published a case of this novel operation which certainly could never have been carried out without the aid of skiagraphy. The operation was performed more than three months after the injury, at the earnest solicitation of the patient, who suffered a good deal from deep cervical pains on the left side and stiffness of the neck. A 3 in. incision was made along the posterior border of the sterno-mastoid muscle in order to gain access to the lateral aspect of the second and third cervical vertebræ. The dissection was continued until the descending fibres of the first bundle of the levator anguli scapulæ were well defined in their upper two inches. The great vessels and nerves were held forward and search was made for the bullet. It could be neither seen nor felt, but the transverse process of the axis was in advance of the next. On holding the pharynx forward the dark bullet was seen buried in the body of the axis. Bone had to be snipped away before it could be extracted. Recovery followed.

THE SCHOOLMASTER ABROAD.

A CORRESPONDENT sends us from Skye an account of a state of matters unfortunately too common—namely, the harm wrought by an utterly ignorant unqualified practitioner. The practitioner in question is a schoolmaster and therefore it is to be hoped a man of some education. Our correspondent, who is a medical man, tells us that he was called to see a patient who had previously been treated by a schoolmaster for an affection of the eye. The schoolmaster said that the patient had an ulcer and gave him a bottle of medicine. Six weeks later our correspondent saw the sufferer and found "intense keratitis and conjunctivitis and in the centre of the cornea a foreign body" which after removal was examined under the microscope and proved to be the scale of a fish. The schoolmaster in question is also said to treat specially girls suffering from amenorrhœa, a statement which may mean nothing or may mean a great deal. He is also understood to receive a fee of 1*s.* for medicine supplied. Now this is a most scandalous state of things, but we are sorrowfully compelled to admit that the chances of stopping such practices are remote. In the first place, the law as it now stands is so impotent that any person whosoever, however ignorant, may treat any patient who is weak enough to go to him, provided only that the self-elected practitioner does not call himself by any "name, title, addition, or description implying that ..... he is recognised by law as a physician," &c., or imply by the use of any title or letters that he is a qualified practitioner. The only method by

Digitized by Google

which he might be brought to justice is by means of a prosecution under the Pharmacy Act and that only if he has sold medicines containing certain poisons mentioned in that Act. Whether the Education Department has any legal right to interfere with the occupations of one of their employés out of school hours is doubtful, but we desire to draw the attention of the department to the fact that a practitioner of this sort is quite as dangerous as a defective drain and infinitely more to be condemned than an absence of hat-pegs.

THE GOLDEN WEDDING OF SIR JOHN SIMON.

WE have the greatest pleasure in offering our congratulations on the occasion of their golden wedding to Sir John and Lady Simon. Few members of our profession have lived a longer life of usefulness than Sir John Simon or can flatter themselves more truthfully that they have contributed largely to the happiness and longevity of others. We fear that the events of the last week must give him some unpleasant impressions of the weakness of our legislators in dealing with great questions of public health. But nothing can efface the work of Sir John Simon or affect the satisfaction with which his friends contemplate the effects of it in this and other countries.

THE CRUDE SEWAGE OF LONDON.

WE have received the report made by Dr. Frank Clowes, chemist to the London County Council, to his council on the bacteriological examination of London crude sewage. The report, though handed to the council by Dr. Clowes, is really the work of Dr. A. C. Houston, who was appointed by the council in February last to coöperate with Dr. Clowes as bacteriologist in the experimental treatment of the crude sewage at Crossness by filtration through coke. The report is only to be regarded as a preliminary statement of the progress of the work, as it would be impossible to adequately deal with the bacteriology of sewage after only a few months' attention. However, it contains a description of some of the methods used in the bacteriological examination of sewage, together with a summary of results of experiments and photographs of some of the bacteria found in London crude sewage, which should be of permanent value to the council's staff at the outfalls as well as to others who are not immediately connected with the council.

A LIVING CHILD DISINTERRED FROM AN ASHPIT.

A CASE presenting several interesting medico-legal features formed the subject of an inquest held by Mr. Birks, coroner for Holderness, Hull, on July 18th. From the report published in the *Eastern Morning News* it appears that the deceased was an unmarried woman, thirty-eight years of age, that she had for seven months been servant to a labourer whose wife was an invalid, and that he did not know she was pregnant. On July 16th she complained of lumbago, but declined to have medical attendance and did her work as usual. On July 17th (Sunday), at dawn, before sunrise—i.e., before 4 A.M.—the man heard her moving about downstairs, and after a few minutes he heard her come up again. He got up about ten minutes past eight, called out to her as he went downstairs, and she said she was a little better and would get up soon. About 11 A.M. he procured the assistance of a neighbour, a woman, to whom the deceased admitted that she had had a child and had buried it in the ashpit; she also said the child "belonged to nobody here," and became unconscious, dying before the arrival of the medical man. There was a great deal of blood about the room. Mr. Edward Harrison, assistant surgeon to the Hull Royal Infirmary, who arrived at the house after the death, found the baby buried in the ashpit covered with ashes and the emptyings of the privy to the depth of about 6 in. He was led to the spot by hearing it crying under the filth. The cord, about 18 in. of which was attached to the child, had been torn through. The child was discovered at 12.10 P.M., and it had probably been there since 3 A.M.—viz., about nine hours. According to the man's evidence it must have been there from 8 A.M., or at least four hours, but from what Mr. Harrison could learn the time was most probably nine hours. The inference was that the child was born before 4 A.M., that the deceased tore through the cord, carried the child downstairs, buried it, and returned to bed, and that hæmorrhage occurred subsequently from partial detachment of the placenta. The post-mortem examination showed very little blood in the body, the heart and great vessels being practically empty. The placenta was in the uterus, the greater part of it being attached to, but easily separable from, the uterine wall; a portion of about the size of the palm of the hand was detached, from which the bleeding had evidently taken place. The perineum was rent as far as the anus. There was no evidence of previous pregnancy. There was a small scirrhus in the left breast. The child was in a vigorous condition on July 19th.

THE LONDON UNIVERSITY COMMISSION.

THE Bill for appointing a statutory Commission to deal with the questions arising from the reconstitution of the University of London passed through the Committee stage of the House of Commons at an early hour on Tuesday morning, and was also allowed a third reading. The amendments which were rejected by the Standing Committee, to which the Bill had been referred, were all again submitted to the House but were again rejected by very large majorities. Sir John Gorst, who had charge of the Bill, refused to consider any amendment which would damage the scheme, and so it has practically passed unaltered through both Houses of Parliament. We still think that a local teaching university distinct from the Imperial Examining Board would have been the better solution of the difficulty, but next to this a dual university under a single Senate is undoubtedly the best plan. We hope that the Commission will soon enter on its duties and that medical students in London will have their present cumbrous system of examinations considerably simplified and be able to obtain degrees on similar terms to those which now exist in the provincial and Scottish universities. After many years of struggle this movement, begun by the late Dr. Moxon and the late Dr. Wilson Fox, appears to have reached a successful issue.

THE SURGICAL TREATMENT OF INTESTINAL TUBERCULOSIS.

THE *Journal* of the American Medical Association, May 21st, 1898, contains a useful paper by Dr. N. Senn, which collates the facts referring to this comparatively novel question. It is only primary and localised intestinal tuberculosis which can be considered suitable for operation. The first method of treatment mentioned is laparotomy and the application of iodoform. It is not strange that this procedure, which has been found successful in peritoneal tuberculosis, should prove efficacious in intestinal. Dr. Senn has no doubt that the use of iodoform is of value in tuberculous peritonitis, for recovery in one case followed its use where laparotomy and drainage had twice failed. To return to intestinal disease. In the case of a child recorded by Nové-Josseraud the cæcum and colon, which were extensively affected, were dusted with iodoform and recovery resulted. Enteroplasty (similar to pyloroplasty of Heineke-Mikulicz for pyloric stenosis) for stricture following the healing of solitary tuberculous ulcer has been

Digitized by Google

successful (Péan). Enterectomy has been performed for intestinal tuberculosis and in well selected cases yields good results. In one case Dr. Senn resected the cæcum and 18 inches of the ileum and performed lateral anastomosis with the aid of decalcified bone-plates. The patient recovered but died six months later from recurrence. But in some cases resection may be too severe an operation; then entero-anastomosis may be performed. It relieves the intestinal obstruction caused by cicatricial stenosis and secures rest for the affected part. In a boy, aged sixteen years, with acute obstruction Dr. Senn performed ileo-ileostomy. The patient recovered and was in almost perfect health two years afterwards. In several cases of tuberculosis of the cæcum entero-anastomosis has been successfully performed by different surgeons.

THE NATIONAL PROTECTION OF CHILDREN.

THE Prince of Wales, in his recent speech at the dinner of the National Society for the Prevention of Cruelty to Children, laid emphasis on the position of the society as an educator. He was able to show that it had in many instances been the means of reviving and stimulating that parental feeling which appears to exist in some degree even in the most cruel father or mother. This result, which, after all, is the ultimate object of the society's creation, is one which many persons are apt to ignore. Mere punishment even as a measure of justice finds, as we have often shown, no place in its system of work. It is the last resort and its aim is always to reform as much as to chastise or to protect. The speech of Lord Herschell on this occasion, the more weighty as being that of one who knows more about the society's affairs than any other non-official person, leaves no doubt on this point. Further, in spite of a sympathy which all must share with the view that needless interference between parents and children is to be avoided, he has arrived at a perfectly clear decision that unfortunately human nature—even that of parents—is still such that the society's operations are indispensable. In common with the Royal chairman he regrets that notwithstanding an increasing revenue as much as one-third of the United Kingdom is still outside the area of its beneficent exertions. At the dinner the sum of £5010 was collected. This more than sufficed to cover a deficit of £2000 which remained to be met. When we reflect, however, that in order to defray last year's working expenses a sum of £53,000 had to be provided, of which £51,000 had been actually subscribed, it will be seen that ample and willing as has been the support accorded to the society, such aid must be largely increased before the required extension of its field of labour can be carried out. The handsome total contributed at the annual dinner may, we trust, be regarded as an augury of increase during the current year.

AT the thirty-first meeting of the Royal Commission on the Water-supply of London, which was held on Monday last in the Guildhall, Westminster, it was decided to adjourn the sittings of the Commission until next November. We shall publish next week our usual full report of the proceedings and we advise those of our readers who are interested in this important question to run through our previous articles on the subject before the sittings recommence. For the water-supply of London is a matter not only of medical importance, but of national urgency.

DR. W. J. COLLINS, late Chairman of the London County Council, was presented on Tuesday afternoon last with a massive silver tray and claret-bowl and two cups. The following inscription was engraved upon the tray:—"Presented to Dr. William Job Collins on the occasion of his marriage, August, 1898, by his colleagues of the London County Council, as a mark of personal regard and of their high appreciation of his services as an able and impartial chairman of the council." The chief officials of the council presented to Dr. Collins a silver bowl.

THE current number of *Punch* has a cartoon from Mr. Linley Sambourne's mordant pencil which will give some halting politicians cause to think. Death with a ready scythe welcomes the new Vaccination Bill brandishing the document in his bony arms and placing his foot on THE LANCET.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund will be held at the Mansion House no Wednesday, Aug. 3rd, to receive the report of the Committee of Distribution and to order payment of awards to hospitals and dispensaries.

DR. CHEADLE, senior physician of St. Mary's Hospital, has presented the medical school with the sum of £500 to found a gold medal in clinical medicine.

THE library of the Royal Medical and Chirurgical Society, 20, Hanover-square, W., will be closed from Aug. 1st to 31st, both days inclusive.

PROFESSOR W. H. CORFIELD, M.D. Oxon., has been appointed honorary sanitary adviser to University College and Hospital.

DANGEROUS TRADES.

(BY A MEMBER OF ONE OF THE ASQUITH COMMITTEES ON DANGEROUS TRADES).

"BUT it was generally the case that when once a difficulty of this kind had to be faced invention came in. It was so in the case of gunpowder in mines. The Home Office had to prohibit the use of blasting powder in certain mines and soon after a simple method of rendering blasting powder harmless was discovered."—Report in daily paper of the Home Secretary's reply to a deputation on the manufacture of phosphorus matches, July 21st, 1898.

IN the sentence I have quoted at the head of this article the Home Secretary has clearly indicated the way in which a solution of the problem of dangerous trades can be found. The attempt to remove the dangers by means of special rules drawn up by the Home Office has proved a failure in all the more serious cases. When Mr. Asquith appointed committees of inquiry in 1893 I think we all believed that we could draw up special rules which would practically remove the evils complained of, but the experience gained since then has shown very clearly that it is only by revolutionising the industries themselves that we can hope to find a remedy of any value. Comparative statistics to support this statement are wanting, but the fact that 1214 cases of industrial lead-poisoning were reported in 1897 alone is sufficient to show that the special rules have failed in their purpose. These figures are the more significant when we find that about 70 per cent. of the cases occurred in industries which have been working under the special rules, and it would probably not be overstating the case if we multiplied these figures by ten in order to arrive at the actual as distinguished from the reported cases.

I am, of course, aware that it may be said that the special rules have never had a fair trial. The public were, I think, surprised to learn the other day from the law officers of the Crown that as the law now stands special rules drawn up by the Home Office have to be submitted to the employer and if he objects to them he can demand arbitration (Section 8, Factory Act, 1891). As any employer affected may do this the Home Office has been forced to frame the special rules so as to suit the wishes of the manufacturers and the result of this has been to weaken these special rules very seriously. A striking example of this is to be found in the special rules drawn up for manufacturers of china. After the chinaware has been dried it is packed with flint dust in large earthenware "saggers" for baking. After the baking is over this flint dust is brushed off the ware by women, the

Digitized by Google

process being known technically as china scouring. During this process this flint dust rises in such dense clouds that I have seen it pouring through an open window like smoke. If this dust is examined under the microscope it is seen to consist of sharp, jagged pieces and Dr. Arlidge has shown that it sets up violent local irritation of the lungs, leading to disease and early death. How long women can live at this employment I do not know, but the belief among the workers in the potteries is that it usually causes death in from two to three years. Now, in the best china factories there is an arrangement of mechanical brushes and fans by which the whole of the dust is removed and never escapes into the room, and it was proposed by the committee of inquiry that such mechanical ventilation should be enforced in all cases of china scouring. This proposal was strongly objected to on the part of the employers on the ground that the smaller manufacturers of china could not afford to put in mechanical power and was consequently struck out of the special rules in their final form and replaced by that convenient word "efficient."

The Home Office are now trying in their new proposed rules to introduce mechanical ventilation for china scouring but are not likely to succeed. There can be no doubt, therefore, that as long as the manufacturers are practically allowed to draw up their own special rules for the Home Office to endorse little improvement can be hoped for, and an amending Act increasing the powers of the Home Office in this direction is urgently needed. It is true there is a clause in the Act of 1895 (Section 28) which was, I believe, intended to give the Home Office the necessary power and seems to do so when read by the layman, but the law officers of the Crown have decided differently.

But while admitting all this it is my special purpose to show that such measures are inadequate and that no arrangements requiring soap and nail brushes to be provided by the manufacturer or overalls and head-coverings to be worn by the workmen are going to remove the dangers caused by the dissemination through the air of compounds of lead or phosphorus. Work in a match factory means constant inhaling of phosphorus vapour, while work in a whitelead works or the dipping-house of a pottery means having the air full of carbonate of lead and getting covered with dust and breathing it in, and getting the clothes, the skin, the hair, and the nostrils loaded with carbonate of lead. If respirators are worn after two or three hours there is more lead inside them than outside them. The first time I saw girls in a whitelead works with their lips white with lead dust I realised the futility of special rules. Such industries must be revolutionised and the problem before us is how to do it. It is, of course, quite useless for the Home Office to make inquiries into the practicability of new processes or to attempt to devise new inventions on their own account. They cannot be competent for such a task, and even if they were could never convince the manufacturer. Let us suppose, for instance, that Dr. Oliver and Dr. Thorpe report, and report quite rightly, that there is no need to use raw lead in glazing earthenware. This will merely remain a pious opinion and will not convince a single potter in Staffordshire. The true way out of the difficulty has been pointed out by the Home Secretary in the quotation at the head of this article. The Home Office must so devise its regulations that it pays the manufacturer better to use an innocuous process. Then what was impossible will become possible and the necessary inventions will be made as soon as there is money in them. Now there are three ways in which this can be done—namely, prohibition, extension of the Compensation Act, and special rules with exemptions.

To take prohibition first, we have already a precedent for this in the Mines Regulation Act, and there is no obvious reason why we should not allow a man to be blown up by gunpowder but permit him to be poisoned by lead or phosphorus. As a first experiment in this direction the Home Secretary might well introduce a short Bill prohibiting the manufacture of matches with yellow phosphorus. The Home Secretary argues against the necessity of this on the ground that the cases of necrosis have been confined to one factory. He should have said the reported cases. Knowing as we do that the discovery of these cases, which had been going on for years, was due to the accident of an inquest and the energy of a newspaper reporter, what confidence can we place in the statement of the Home Secretary that such cases have not occurred elsewhere? It is surely a remarkable fact that phosphorus should confine itself to attacking only the workers in the factory which happens to be investigated by those outside the official ring.

A thorough inquiry will, I believe, show that there is a very strong case here for prohibition, while the trade to be dealt with is so small and the inconvenience to the public so slight that we could hardly take a better case for our first experiment. The whole number of match factories in the country amount to 25 and the whole number of men, women, and children employed amount to 3610. Many of these are already making safety matches and if proper notice were given the remainder could be similarly employed. Then we have no reason to believe that a "strike anywhere" match without yellow phosphorus cannot be made. Receipts are given in the technical books and the minute that there is money in a match without phosphorus plenty will be forthcoming. I should not be surprised to find that the mere threat of prohibition started match manufacturers experimenting and that since the Home Secretary's speech on July 21st all such experiments have ceased.

The next step proposed is the extension of the Compensation Act so as to cover injuries to health as well as accidents. This was proposed by Mr. Asquith as the Bill was passing through the House of Commons and Mr. Hedderwick has brought in a short Bill this year with the same object. The best plan probably would be to take such injuries to health as have been scheduled by the Home Office and of which returns have to be made, such as lead, phosphorus, and anthrax poisoning, and bring them under the operation of the Act. Such an extension of the Act would stimulate enormously the invention of innocuous substitutes for lead and phosphorus. For instance, the whitelead works would find themselves faced with such a heavy charge for insurance that instead of opposing the introduction of whitelead substitutes they would begin to use their enormous resources and vast trade connexions to introduce such substitutes themselves. Several good substitutes are known and few of them are now protected by patent, the inventors having failed miserably in their attempts to introduce them. So the way is open and the change will be made if there is money in it.

The third proposal is the drawing up of special rules with exemptions. An example taken from the pottery industry will perhaps show most clearly how this can be done. It is usual in the operations connected with dipping and printing the ware to employ a considerable number of children and young persons, who are thus brought in contact with lead in the soluble form of the carbonate. On the other hand, it has been shown by the firm of Mintons that the lead can quite well be fused before use into a glass or frit consisting of borates and silicates of lead, which if properly prepared are practically insoluble in the stomach. Furthermore, it has recently been proved that it is possibel to make a satisfactory leadless glaze. Yet in spite of the examples of Mintons before them, who have successfully fritted their lead for years, the pottery manufacturers refuse to give up the use of carbonate of lead. This may ultimately be a case for prohibition, but in the meantime a great deal could be done by raising the age of those employed in contact with lead from fourteen to eighteen years and granting exemption from this rule to those potters who have adopted a glaze which the Home Office after examination has passed as innocuous. This would so increase the cost of manufacture from the higher rate of wages to be paid that lead frits or leadless glazes would probably be quickly adopted. There are many other trades in which a similar plan might well be tried.

I have now, I think, sufficiently developed and replied to the text for which I have to thank the Home Secretary and may add a word or two about the Home Office itself. The factory department of the Home Office had formerly little to do beyond registering the ages and hours of work of women and children and ordering the fencing of machinery. But gradually it has been dawning on the public that a large number of industries on which our national wealth depends and in which a large proportion of our people are employed are carried on in a way which is injurious to health and that we may be paying too high a price for our manufacturing supremacy if we maintain it at the cost of the vitality of the race. Naturally we appeal to the Home Office to set such matters right and by this process the factory department, once an insignificant portion, is finding itself with much groaning and unwillingness converted into a vast department of public health in charge of some of the most vital problems dealing with the nation's welfare. Now for such a department of public health expert knowledge and expert training are necessary. The first step in the right direction was taken in the appointment of a distinguished public

Digitized by Google

health officer to the head of the department. But this is not enough. Both inside and outside the department as inspectors and as officials we should have medical men thoroughly trained in public health work who might, if necessary, combine the duties of factory inspectors and certifying surgeons, and if, at the same time, the committee of inquiry into dangerous trades, which is still sitting, is made into a permanent bureau for the collection of accurate information the factory department of the Home Office will be capable of dealing with the enormous field of work before it and become the guardian of our public health.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

THE Secretary of State has made the following further appointments of medical referees under the Workmen's Compensation Act, 1897:—

Circuit No. 5.—Dr. Frederick Blakesley Mallett, Bolton; Dr. James Corns, Oldham; Dr. James Holmes, Manchester; and Dr. Joseph Henry, Rochdale.

Circuit No. 8.—Dr. William Thorburn, Dr. Samuel Buckley, Dr. Abraham Emrys Jones, Mr. Judson Sykes Bury, Mr. George Arthur Wright, and Dr. Simeon Holgate Owen, Manchester.

Circuit No. 13.—Mr. Rutherfoord John Pye-Smith and Mr. Archibald William Cuff, Sheffield; and Dr. Henry Waytes Pomfret, Manchester.

Circuit No. 14.—Mr. Walter Thompson, Mr. Walter Henry Brown, and Mr. Charles James Wright, Leeds; and Mr. William Kitson Clayton, Wakefield.

Circuit No. 16.—Dr. Charles H. Milburn and Mr. Thomas Melancthon Evans, Hull; Mr. John Dickinson Leigh, Scarborough; and Dr. John Fletcher Horne, Barnsley.

Circuit No. 26.—Mr. Matthew Arden Messiter, Dudley; Mr. Thomas Vincent Jackson, Wolverhampton; Mr. Henry William Langley Browne, West Bromwich; Mr. George Arthur Phillips, Walsall; and Mr. Christopher Atkinson Newnham, Wolverhampton.

Circuit No. 33.—Mr. Charles Hunter Graham, Lowestoft; and Dr. William Alfred Elliston, Ipswich.

Circuit No. 40.—Mr. George Paddock Bate, 412, Bethnal Green-road; Mr. Frederick John Smith, 4, Christopher-street, Finsbury-square; and Mr. Bertram Goddard, 27, Pentonville-road.

Circuit No. 41.—Mr. Alfred Herbert Tubby, 25, Weymouth-street, Portland-place; and Mr. H. Martin Jordan, 9, John-street, Adelphi, W.C.

Circuit No. 45 (further appointment).—Mr. Felix Charles Kempster, 79, Bridge-road, Battersea.

Circuit No. 49.—Dr. Thomas Whitehead Reid, Canterbury; Dr. Charles Parsons, Dover; Dr. Thomas George Styan, Ramsgate; and Mr. James Vincent Bell, Rochester.

Circuit No. 50.—Mr. Ebenezer Snell, Brighton.

Circuit No. 54.—Dr. Bertram Mitford Heron Rogers, Clifton; and Mr. James Paul Bush, Clifton.

Circuit No. 58.—Dr. J. Raglan Thomas and Dr. John Woodman, Exeter; Mr. John Henry Square May and Mr. Charles Hamilton Whiteford, Plymouth; and Mr. J. Snowden Smith, Tavistock.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6423 births and 3356 deaths were registered during the week ending July 23rd. The annual rate of mortality in these towns, which had been 14·7 per 1000 in each of the two preceding weeks, rose again last week to 15·6. In London the rate was 15·4 per 1000, while it averaged 15·7 in the thirty-two provincial towns. The lowest rates in these towns were 4·6 in Croydon, 10·7 in Huddersfield, 10·9 in Hull, and 11·3 in Nottingham and in Halifax; the highest rates were 18·9 in Birkenhead, 19·6 in Gateshead, 21·1 in Liverpool, and 23·9 in Salford. The 3356 deaths included 487 which were referred to the principal zymotic diseases, against 330 and 378 in the two preceding weeks; of these, 220 resulted from diarrhœa, 93 from whooping-cough, 70 from measles, 53 from diphtheria, 26 from "fever" (principally enteric), 25 from scarlet fever, and not one from small-pox. No death from any of these diseases was recorded last week in Huddersfield or in Halifax; in the other towns they caused the lowest death-rates in Nottingham, Bolton, and Croydon, and the highest rates in West Ham, Norwich, Birkenhead, and Salford. The greatest mortality from measles occurred in Plymouth and Norwich; from whooping-cough in West Ham, Preston, Oldham, and Newcastle-upon-Tyne; from "fever" in Burnley; and from diarrhœa in Portsmouth, Birmingham, Birkenhead, and Salford. The mortality from scarlet fever showed no marked excess in any of the large towns. The 53 deaths from diphtheria included 29 in London, 6 in Leeds, 3 in West Ham, and 3 in Liverpool. No fatal case of small-pox was registered last week either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, July 23rd, was 2355, against 2205, 2250, and 2314 at the end of the three preceding weeks; 276 new cases were admitted during the week, against 204, 237, and 265 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 160 and 175 in the two preceding weeks, declined last week to 148, and were 31 below the corrected average. The causes of 29, or 0·9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Hull, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Burnley, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 21·1 to 18·5 per 1000, rose again to 20·1 during the week ending July 23rd, and exceeded by 4·5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·2 in Aberdeen and 16·4 in Leith to 22·7 in Paisley and 23·8 in Perth. The 605 deaths in these towns included 55 which were referred to diarrhœa, 29 to whooping-cough, 19 to measles, 8 to scarlet fever, 5 to "fever," and 2 to diphtheria. In all, 118 deaths resulted from these principal zymotic diseases, against 96 and 93 in the two preceding weeks. These 118 deaths were equal to an annual rate of 3·9 per 1000, which was 1·6 above the mean rate last week from the same diseases in the thirty-three large English towns. The 55 fatal cases of diarrhœa showed a further increase upon recent weekly numbers, and included 38 in Glasgow. The deaths referred to whooping-cough, which had been 21 and 26 in the two preceding weeks, further rose to 29 last week, of which 10 occurred in Glasgow, 9 in Edinburgh, and 4 in Dundee. The fatal cases of measles, which had declined from 41 to 23 in the two preceding weeks, further fell to 19 last week, of which 9 were recorded in Glasgow and 6 in Dundee. The 8 deaths from scarlet fever were within one of the number in the preceding week, and included 5 in Glasgow and 3 in Edinburgh. The 5 fatal cases of "fever" corresponded with the number in the preceding week, and included 2 in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 106 and 76 in the two preceding weeks, were 75 last week, and were 12 below the number in the corresponding period of last year. The causes of 32, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the four preceding weeks from 22·8 to 18·5 per 1000, rose again to 22·7 during the week ending July 23rd. During the past four weeks the rate of mortality in the city has averaged 20·8 per 1000, the rate during the same period being 14·6 in London and 20.0 in Edinburgh. The 152 deaths registered in Dublin during the week under notice showed an increase of 28 upon the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 6 and 3 in the two preceding weeks; of these, 5 resulted from whooping-cough, 4 from diarrhœa, 1 from scarlet fever, 1 from diphtheria, and 1 from "fever." These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 2·0 in London and 3·2 in Edinburgh. The fatal cases of whooping-cough, which had been 3 and 1 in the two preceding weeks, rose again to 5 last week. The 4 deaths from diarrhœa exceeded the number in any recent week, and the mortality from scarlet fever corresponded with that recorded in the preceding week. The 152 deaths in Dublin last week included 38 of infants under one year of age, and 31 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in the preceding week. Seven inquest cases and 2 deaths from violence were registered; and 64, or more than a third, of

Digitized by Google

the deaths occurred in public institutions. The causes of 11, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NAVAL MEDICAL SERVICE.

FLEET-SURGEON GEORGE ROBERT DEIGHTON CHARLTON has been placed on the retired list of his rank at his own request. Fleet-Surgeon Thomas Canning Hickey retires with the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are announced: — Staff Surgeons: H. J. Hadden to the *Rainbow* and A. G. Andrews to the *Thunderer*. Surgeons: John W. Craig to the *Heron*, Edward T. Meagher to the *Caledonia*, and John C. Durston to be lent to the Walmer depôt. Surgeon and Agent: Arthur B. Vise at Fosdyke Station and Fleethaven.

ROYAL ARMY MEDICAL CORPS.

Major Nicholas retires on retired pay. Lieutenant-Colonel G. A. Hughes and Major J. M. Irwin have embarked for service in Egypt. Lieutenant-Colonel C. Douglas, V.C. (retired pay), takes over charge of the Station Hospital, Perth. Lieutenant R. Fawssett is directed to rejoin the Home District. Captain R. J. D. Hall has embarked for Egypt. Captain Bewley is placed under orders for Hong-Kong.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel Slaughter (Army) to officiate on the Administrative Medical Staff of the Army, with the temporary rank of Surgeon-Colonel, vice Surgeon-Colonel Williamson (Army), deceased. The Viceroy and Governor-General has been pleased to make the following appointments on His Excellency's personal staff:—Surgeon-Colonel Warburton, vice Brigade-Surgeon-Lieutenant-Colonel Cunningham, retired; Surgeon-Colonel Price (Army), vice Surgeon-Colonel Atkins, vacated; and Brigade-Surgeon-Lieutenant-Colonel G. D. Bourke (Army), vice Brigade-Surgeon-Lieutenant-Colonel Edge, vacated. Surgeon-Lieutenant-Colonel J. P. Greany and Surgeon-Lieutenant-Colonel Davidson have respectively delivered over and received charge of the Dharwar Prison. The services of Surgeon-Captain Gabbett (Madras) are replaced at the disposal of the Government of Madras. Surgeon-Captain Grant, (Bengal) is appointed to officiate as Residency Surgeon and *ex-officio* Assistant to the Resident in Nepal, vice Surgeon-Captain Armstrong, on leave, until further orders, and Surgeon-Lieutenant-Colonel Hall, Officiating Inspector-General of Civil Hospitals, North-West Provinces and Oudh, is appointed to hold charge of the office of Inspector-General of Prisons, North-West Provinces and Oudh, in addition to his other duties, from the date of taking charge.

VOLUNTEER CORPS.

Royal Engineers: 1st Gloucestershire: Surgeon-Lieutenant W. B. Fergusson to be Surgeon-Captain. *Rifle:* 3rd Volunteer Battalion the Queen's (Royal West Surrey Regiment): Josiah Field Hall to be Surgeon-Lieutenant. 3rd Volunteer Battalion the Welsh Regiment: The retirement of Surgeon-Major Evan Jones is cancelled.

THE SPANISH-AMERICAN WAR.

Until Wednesday there had been a comparative lull in the news and progress of events since the destruction of Admiral Cervera's fleet and the capitulation of the Spanish garrison of Santiago and the capture of that place by the Americans. On that day, however, news came that the Spanish Government had through the French Ambassador asked for a cessation of hostilities in order that terms of peace might be considered. A difficulty with which the United States Government are at present confronted is with respect to the Cuban insurgents and the future policy to be adopted in regard to them and to the island and its inhabitants, who have set up a claim for the establishment of a Cuban Republic. It will be very interesting to know how the Washington Cabinet will deal with the various and rather difficult problems which must have been foreseen from the first but with which they are now face to face. Meanwhile the war is going on, the invasion of Puerto Rico has begun, and the fall of Manila must soon occur. The American troops in and around Santiago have suffered greatly from heat and malaria and there are a large number of sick. This gives rise to a large amount of extra work falling upon those remaining well in the way of guards and night duty, and the physical strain entailed on the troops in these respects, unless soon relieved, must probably be followed by an increased amount of ineffectiveness from fatigue and sickness. Sanitary precautions and measures are being carried out on a large scale, but these necessarily take time to effect. The Americans will lose no opportunity, we may feel assured, of camping as many of their troops as possible in any available uplands in the vicinity of Santiago and in transporting to America such invalid soldiers as are not soon likely to render effective service in the field. Those engaged in ambulance work about Santiago must have had a trying and perilous time of it according to a letter written by Mrs. Porter, the wife of President McKinley's secretary, who went to Santiago with the Red Cross Society. Mrs. Porter writes on July 8th describing the measures taken in the aid and care of the wounded and says: "The Spanish wounded captives expressed much gratitude at being given the same attention as the Americans. In several cases wounded men were shot dead as they lay in the Red Cross litters *en route* to the hospitals. This firing upon the wounded and those who were caring for them so increased that the surgeons operated by moonlight, being afraid to light candles or lanterns lest the Spanish sharpshooters should pick them off."

A FRENCH ARMY SURGEON'S EXPERIENCE OF INFLUENZA.

Duplay's *Archives* for July contain two articles by military medical officers—to wit, an "Epidemiological Study" of Influenza and the Diseases that may be Evolved Simultaneously, by Surgeon-Major J. Marty, and the first part of a critical essay on Chloroma or green cancer by Assistant-Surgeon Gustave Lang. Quoting Fuster in Rochard's Encyclopædia of Hygiene Surgeon-Major Marty enumerates as follows the epidemics of influenza which have received historical notice since A.D. 1239: thirteenth century, 1; fourteenth, 6; fifteenth, 7; sixteenth, 17; seventeenth, 12; eighteenth, 28; and nineteenth (up to 1860), 21. Since 1860 several additional epidemics have been noted, so on the whole it is more than probable that the record for our expiring century will largely exceed that of its predecessor. Up to 1892, says Surgeon-Major Marty, atmospheric and meteorological vicissitudes were universally regarded as the cause of influenza, but Pfeiffer's bacillus, discovered in that year, soon came to be acknowledged as the specific agent of the affection, and although the researches of Tessier, Roux, and Pittion raised some doubts on the subject the general belief has not been seriously disturbed. At the same time, as was pointed out in 1895 by Bezançon in *La Médecine Moderne*, Pfeiffer's bacillus is habitually found associated with other microbes which no doubt are more or less concerned in the evolution of the malady, and the true etiology of the latter can only be arrived at through a comprehensive study of all the micro-organisms collectively as well as individually. Surgeon-Major Marty's remarks are based on his experiences at Chollet, where he was quartered for three years, from 1892 to 1895. During this period there were three distinct epidemics of influenza, each one furnishing examples of the nervous, the thoracic and the gastro-intestinal forms of the disease. The numbers are too small for generalisation, but so far as they go the deductions drawn from them are interesting. The influenza bacillus can live amicably with many of its congeners and the latter are responsible for many of the incidental phenomena. There is, however, nothing harder than to draw a line where the effect of one microbe ends and that of another begins. They all react upon each other, but the possibility of coincidence must not be forgotten.

MEDICAL INSPECTION OF FRENCH SOLDIERS PROCEEDING ON FURLOUGH.

According to a decree which was issued in October, 1892, the medical inspection of all French soldiers quitting the service for any cause or proceeding on temporary leave of absence is strictly enjoined, but apparently the latter part, at all events, of the edict has never been acted upon, being regarded as a purely theoretical ordinance. Be this as it may, a supplementary decree, dated May 6th, 1898, has now been promulgated to the following effect: "1. Soldiers desirous of obtaining leave of absence shall be inspected by a medical officer, and if found to present symptoms of any disorder, however slight and non-contagious, they shall be detained with their corps. 2. In cases when soldiers may be

Digitized by Google

granted permission as an exceptional measure to return to their families for medical treatment, commanding officers shall grant leave of absence for a period in accordance with the probable duration of the disease, but not until they have satisfied themselves that the families are in a position to receive their relatives." The Minister of War's instructions on the foregoing run as follows: "The decree is designed, so far as possible, to prevent soldiers proceeding on leave of absence while in the incubative stage of disease. The neglect of this precaution might at any moment lead to overcrowding in the civil hospitals or to sick soldiers whose state did not permit of their reception and treatment among their friends being left without an asylum."

THE HEALTH OF THE JAPANESE NAVY.

The Director-General of the Japanese Imperial Navy has just issued his report for the twenty-eighth year of Meiji (1895). The general health he states to be satisfactory. The returns of the number of cases of disease show a decrease of 53·96 per 1000, while the ratio of each day's sickness shows an increase of 0·36 per 1000 of the force when compared with the previous year. As the battle of Wei-hai-wei and the rebellion of Formosa occurred in 1895 the number of casualties was naturally greater than in an ordinary year. The ratio of cases of venereal disease and their sequels was 152·39 per 1000. The mean daily force in service for the year was 13,006 men, an increase of 2003 men over the previous year. Of the total number of 13,006 men 0·02 per cent. were under the age of fifteen years, 5·73 per cent. were between the ages of fifteen years and twenty years, 38·30 per cent. between the ages of twenty years and twenty-five years, 31·58 per cent. between the ages of twenty-five years and thirty years, 18·90 per cent. between the ages of thirty years and thirty-five years, 4·32 per cent. between the ages thirty-five years and forty years, 1·05 per cent. between the ages of forty years and forty-five years, and 0·10 per cent. between the ages of forty-five years and fifty years. As the terms of service were lengthened by the Japan-China War there were some men over forty-five years of age.

SURGEON GENERAL TAYLOR.

Surgeon-General Taylor, R.A.M.C., has, as we have stated, been selected for the appointment of Principal Medical Officer of the Anglo-Egyptian force in the forthcoming advance on Khartoum and is probably in Egypt at the present time. We presume that the size and importance of the expedition and the strength of the British contingent taking part in it were considered to be such as to warrant and require the appointment of an officer of high rank in medical charge of the expeditionary force and its sanitary and hospital arrangements in the field.

DEATHS IN THE SERVICES.

Surgeon-General William Johnston, I.M.S., Madras (retired), at his residence, Cheltenham, on July 24th. He served throughout the Chinese War and was present in ten engagements (medal with clasp). For many years he was deputy inspector of hospitals in the Madras presidency. He retired in 1876.

The appointment of Secretary to the Principal Medical Officer of Her Majesty's Forces in India will, we understand, become vacant on Aug. 14th by extended time expiration in the post of Surgeon-Colonel Beatson, 9th Bengal Cavalry, who will be succeeded by Surgeon-Major Shearer, 27th Punjab Infantry, late in medical charge of the 63rd Native Field Hospital.

THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.—Founder's day was celebrated on Monday, July 25th. The Rev. T. N. Hart-Smith presided, and among those present were Dr. T. W. Shore, Sir Joseph Fayrer, Dr. Holman, Dr. Lumsden Propert, Dr. Baines, Mr. Kiallmark, Colonel Gordon Watson, Mr. H. E. Vardon, Mr. Clement Smiles, and Mr. A. Oldaker. In his address the headmaster, the Rev. T. N. Hart-Smith, called attention to the large number of scholarships connected with the college and referred to the favourable alterations recently made in the conditions under which they were awarded. Dr. Shore, Warden of St. Bartholomew's Hospital Medical School, bore testimony to the excellence of the education given at Epsom College.

Correspondence.

"Audi alteram partem."

THE RECTAL INJECTION OF THE SERUMS.

To the Editors of THE LANCET.

SIRS,—In the treatment of diphtheria I have successfully employed a method of sero-therapy which has, so far as I am aware, not yet been brought under the notice of the medical faculty in this country. In this borough, and I think in most places where anti-vaccination precepts are rampant, any method of procedure which to the uninitiated savours of what our opponents are pleased to term the "Jennerian ritual" is certain to meet with most unreasonable and bigoted opposition. This spirit of interference is habitually manifesting itself in a stubborn refusal on the part of parents to allow their children to be treated with anti-diphtheritic serum. I think, however, that it is in large measure the method of administration which attracts the attention and calls down the anathemas of these parents. I was, therefore, last year tempted to inject sera *per rectum* instead of hypodermically and with such gratifying results that I see no reason to revert to the ordinary method of administration. So far I have not had a sufficient number of cases under my care to enable me to adduce evidence of any real value for statistical purposes, but I consider it expedient at this early stage to direct the attention of colleagues to what appears to be a simple method of employing a most excellent remedy. Certain it is that no harm can accrue through administering antitoxin by the bowel if the diagnosis is established and if the ordinary rules as to posology and aseptic preservation of the serum are observed. I have not seen a single case of rash or other complication which could reasonably be attributed to the serum. Such complications are, I believe, almost invariably caused by the coinjection of adventitious organisms or their products and it is at least possible that many of these would fail to pass through the rectal mucous membrane. The serum itself, judging by results, appears to undergo rapid and complete absorption, so that I have observed the usual posological rules. A difficulty with which many provincial practitioners have to contend is to procure fresh serum expeditiously. It deteriorates rapidly if kept and the twenty-four hours' delay which perhaps ensues before it can be obtained fresh may determine a case. For this reason dried serum has commended itself, but I think most practitioners will agree with me that its viscidity when dissolved interferes with its hypodermic injection—that is, unless it be mixed with an inconveniently large volume of water. Moreover, it is by no means easy to ensure its sterility when mixing it. If, however, we administer it *per rectum* these two difficulties vanish and it becomes, *cæteris paribus*, the ideal serum for provincial practitioners.

Briefly, the advantages of rectal over hypodermic serotherepy appear to be as follows: (1) It can be employed in almost all cases without fear of prejudicial interference; (2) solid sera can be conveniently used; (3) it is expeditious and simple; and (4) the absorbed serum is purer. I have also administered anti-streptococcic serum per rectum with gratifying result in a case of scarlet fever. Reasoning by analogy the method appears to be deserving of trial, and should my expectation as to its general employment in the near future be verified we may possibly hear of some enterprising firm supplying solid sera in the form of suppositories. The adduction of experimental as well as clinical evidence as to the absorption of sera and, indeed, of lymph by mucous membranes would be pregnant with interest.

I have the honour to be, Sirs, yours faithfully,

J. E. O'CONNOR, M.B. R.U.I.,
Physician to the Lowestoft Isolation Hospital.

Lowestoft, July 21st, 1898.

"ONLY A PAUPER."

To the Editors of THE LANCET.

SIRS,—I notice that you have in THE LANCET for the second time cast a slur on what you term the Marylebone infirmary workhouse. There is no such place as the Marylebone

Digitized by Google

infirmary workhouse and your comments in THE LANCET of July 16th might give a false impression to many ignorant persons who would not distinguish the difference between a workhouse infirmary and an ordinary workhouse such as the Gray's Inn-road workhouse. The case reported in THE LANCET of June 25th occurred at the latter place, which is only a temporary workhouse and over three miles from the infirmary. The nurses here, 74 in number, are all fully trained as required by the Infirmary Committee and the committee of the Nightingale Fund, and they are, as acknowledged by many of the leading medical men in London and as shown by the important posts they get after their three years' training here, as well qualified as those trained at any hospital. I should be glad if you will be careful in future not to speak of the Marylebone workhouse as the Marylebone infirmary workhouse and should be grateful if you will come and inspect our wards, when you will see for yourselves that the "paupers," as you call them, have every care, comfort, and kindness that medical skill and good nursing can bestow upon them. In the meantime I beg to enclose a few papers which may give you a small idea of what is required of our nurses. I am, Sirs, yours faithfully,

JOHN R. LUNN,
Medical Superintendent.

St. Marylebone Infirmary, July 23rd, 1898.

*** We are sorry that the mistake should have occurred.—ED. L.

"THE DRAINAGE OF SWANAGE."

To the Editors of THE LANCET.

SIRS,—Allow me to supplement Dr. McCausland's admirable letter of July 19th[1] by the following short account of the deaths here during the three last completed years 1895-96-97. They number 107, which gives 16 per 1000 for the population. On analysis 43 were of those seventy years old and over, 25 of children one year old and under, 5 were the result of accident, 5 were cases of cancer, and 5 died from phthisis, leaving 24 deaths during three years in a population of over 2500 from all other causes—results for which any town may be thankful. Party quarrels and rival interests, I am sure you will admit, should not be allowed to intrude into these questions. The "sanitary defects pointed out by Dr. S. W. Wheaton in his report of 1897" *do not remain*, and this is the seriousness of the charge you have made. I am, Sirs, yours faithfully,

Swanage, July 25th, 1898. EDWARD CALTHROP.

"BONE-SETTERS AND THE EMPLOYERS' LIABILITY ACT."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent, Mr. John Cranke, I beg to say that I have had considerable experience of cases under the Employers' Liability Act, having until recently held the office of consulting surgeon for such cases to several large unions representing in the aggregate about 100,000 men. Your correspondent's questions are entirely legal ones and as such can be better answered by a solicitor. My experience in cases under the Employers' Liability Act is that the question to be settled is mainly how long the man has been or is likely to continue to be disabled, and that the compensation is settled on that basis—assuming that the man is legally entitled to any compensation at all, and this latter question the practitioner is not called upon to decide. In estimating the recovery of a man the question is *not* when will it be possible for the man to work, but when will he be certainly able to do his usual work as well and with the same ease as before the accident, providing the nature of the injury permits of such recovery within a reasonable period; in other cases the question of the man's ability to do (and obtain) light work will arise.

Personally I have never heard the question raised in court as to how far a man's misjudgment in the selection of a medical adviser who may have retarded his recovery has any effect on the employer's liability. So far as I can judge, however, there is little or no doubt that the employer would be held responsible for the full compensation, including the further injury done by the medical adviser—bone-setter for instance—on the ground that the patient in calling in the medical adviser (bone-setter) acted in good faith and certainly would not have done so had the accident not occurred. Assuming that your correspondent means the "Workmen's Compensation Act, 1897," when he speaks of the "new Act," I certainly think that under that Act the compensation will be largely, if not entirely, settled on the same basis; but this again is a purely legal question. With regard to protection generally the General Medical Council is proverbially slow to act and in this particular case the bone-setter in question does not appear to have represented himself as a registered medical practitioner and I do not think that in the present state of the law he can be prosecuted. Worse luck!

I am, Sirs, yours faithfully,

Ilford, July 25th, 1898. MURTAUGH HOUGHTON.

[1] THE LANCET, July 23rd, 1898, p. 228.

THE TREATMENT OF GOUT BY PIPERIDINE.

To the Editors of THE LANCET.

SIRS,—I was much interested in the paper of Dr. Tunnicliffe and Dr. Rosenheim on Piperidine as a Uric Acid Solvent contained in THE LANCET of July 23rd and consider that the authors deserve every credit for their laborious and painstaking investigation. Undoubtedly the experiments described in the paper show that piperidine may be of use in cases of uric acid gravel and calculi as a solvent of uric acid on the distal side of the kidneys, and the experiments also show that the drug is in such respects superior to piperazine, but the value of the drug as a solvent of gouty deposits is, in my opinion, by no means proved. Dr. Tunnicliffe and Dr. Rosenheim state that the tartrate of piperidine may be given in doses of 15 grains three times a day. Now, if 15 grains of piperidine were introduced at once into the circulation of an adult man of average weight the percentage of the drug in the blood would be about 0·002, yet the only experiments conducted by the authors as to the solvent effect exerted by piperidine on sodium biurate are with 0·1 per cent. solutions, or with fifty times as much as could be introduced into the circulation by ordinary dosage. My experiments described in THE LANCET of June 11th, 1898, showed that piperazine and other drugs, when present in far larger proportions than could be introduced into the blood by medicinal administration, did not increase the solvent power of artificial blood serum for gouty deposits. The results of my experiments confirm those obtained by Sir William Roberts and by Dr. Levison of Copenhagen, and are also supported by my clinical experience. Dr. Tunnicliffe and Dr. Rosenheim state that "there seems little doubt that uric acid is normally present in blood." If they will refer to the comparatively recent results of von Jaksch, Klemperer, Sir Alfred Garrod, and myself they will learn that there is considerable doubt as to the normal presence of uric acid in the blood. Dr. Tunnicliffe and Dr. Rosenheim have certainly estimated something in bullocks' serum, but they do not mention whether they identified the body as uric acid by the murexide test.

I am, Sirs, yours faithfully,

ARTHUR P. LUFF, M.D. Lond.

Weymouth-street, W., July 26th, 1898.

THE HUXLEY LECTURE.

To the Editors of THE LANCET.

SIRS,—I shall feel very much obliged if you can kindly find a corner in THE LANCET for a statement of the fact that the Huxley Lecture which Professor Virchow is to deliver on Monday, Oct. 3rd, will be *in English*, as there seems to be so much doubt on the point, notwithstanding the very clear intimation which you gave in your issue of July 16th.

I am, Sirs, yours faithfully,

H. MONTAGUE MURRAY,

July 23rd, 1898. Dean of Charing-cross Hospital Medical School.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET

SIRS,—With some reluctance I venture to trespass once again upon your space. The above is, however, a subject which deserves and is now receiving a large amount of

Digitized by Google

our attention. Your able leading article draws attention to a very important point—that the newly qualified man has been only familiar with men at the head of their profession who enjoy considerable incomes and is apt unthinkingly to apply similar standards of luxury to members of the profession generally. Now there is surely a great difference between the newly qualified and the long qualified man; the former has nearly everything to learn so far as the actual details of practice go; the latter may be an invaluable help to his principal. Most medical men are in such a position that they cannot possibly afford to keep an elderly assistant and so have to do all the important work themselves.

"Another G. P." sympathises with us who get so small a return for our labour. While fully agreeing with most of his letter, I fail to see that I was squeezed by my late principal who paid me £80 in-door. I was satisfied, although I had previously held some important hospital appointments, and I consider that from £80 to £100 in-doors, gradually increasing slightly, is as much as any assistant is worth to a country practitioner.

"Practitioner Too" and also "Another G.P." are anxious to hear some of the details as to clubs, parish work, &c. Both my own practice and also that of my late principal have been practically free from clubs; the few members that either of us had averaged 5*s.* per annum for attendance on the member himself. The parish work was practically *nil* and the remuneration received for it was consequently more than adequate. A fee of 2*s.* 6*d.* was and is the lowest fee charged either in the surgery or for a visit save only in a few exceptional cases. The general fees were charged according to the tariff of various branches of the British Medical Association, but it is one thing to charge and another to be paid. Many of my patients live six miles away, some of them twelve. It is a very scattered district and I am the nearest medical man. The population could not possibly support another. How do your readers expect a labourer earning 10*s.* per week and his food to pay me adequate fees for a twenty-mile journey? This point always suggests to me the possibility of State payment in such cases, especially for attending infectious diseases where our chief aim is to protect the public. We must remember that the medical officer of health is not expected to attend the patient, and is, therefore, not always in a position to say when infection is over. My own expenses could be considerably cut down in the matter of horseflesh by refusing to attend these impecunious long-distance cases, but what is to become of them? Another point is, I consider it high time that the members of the profession awoke in a mass from their lethargy with regard to bad debts in cases where there really is money to pay.

I have explained that this practice is almost devoid of clubs and ridiculously small surgery fees, though I question very much whether the club doctor does not get more adequate return in the long run than we who have to whistle for our money. I will give one instance of where the long distances make the life one of slavery. I have just received the sum of £1 4*s.* for vaccinations performed as public vaccinator; the fees were sufficient for the work performed if it had been done at home, but I was allowed nothing for travelling though I was expected to drive 72 miles to attend the various stations. Your correspondents appear to think my figures extreme and I will allow that there are a few special circumstances, unconnected with myself and which cannot be disclosed, which certainly make my income a little less than it otherwise would be. To my mind bad debts are quite as much to blame as small fees, and if things go on as they are we shall almost certainly have to consider the necessity of either some form of State aid in scattered districts, or compulsory collection of debts, or a wholesale club system at reasonable fees for all working men and their wives and families. If assistants will only consider the matter fairly I feel sure that they will see no necessity to complain of being squeezed by their principals. It is the profession which is being squeezed by the public, and the assistants are in many cases the only ones who are unable to feel the pressure, for they are housed and fed and should surely be able to save something out of £80 or £100. The numerous societies to which we subscribe should be sufficient to safeguard our interests and we must look to them to do it.

One other point: how much would the qualified assistants who are now sneering at a remuneration of £100 in-door be willing to accept from hospital authorities for a house surgeoncy? We have heard very little of the gratuitous or almost gratuitous services rendered in these institutions, but surely it is here that the battle should commence. Here the funds come from the public and it is indeed hard that the public should be let off and the hard-worked practitioner expected to pay large sums for similar services and at the same time bear all responsibility. I have in my mind at the present moment a case in which the principal had to pay nearly £100 for a mistake made by a qualified assistant. If it were not for the long distances I should be satisfied with my income, but it is just these awful journeys which cost the time and money and make up the chief difference between the town and country practitioner. An actual income of £400 represents a far larger amount of bookings, but the latter are of no use without the cash.

I am, Sirs, yours faithfully,

July 24th, 1898. PRACTITIONER.

To the Editors of THE LANCET.

SIRS,—Just now we are hearing a good deal in the columns of THE LANCET and elsewhere concerning the alleged dearth of qualified assistants, the alleged multiplication of poor principals who cannot afford to pay a decent salary, and the alleged dead-lock caused by the recent *pronunciamiento* of the General Medical Council, which numbers the unqualified assistant among the things that were. That the unqualified assistant was an unqualified nuisance, will, I think, be denied by few, save those whose judgment is biased by self-interest. That well-educated and self-respecting young gentlemen should decline to undertake arduous duties for salaries less than the wages of an upper servant is not surprising. That the acceptance of contemptible fees for responsible professional services is degrading to the individual and derogatory to the dignity of a learned profession is abundantly evident. That side by side with the alleged dearth of assistants there is an undoubted plethora of practitioners is shown by the yearly growth of the Register.

If these things are so the question arises, Is there any practical remedy for this sufficiently grave state of matters? I believe that there is such a remedy, though at first sight it may appear an anomalous one. It is this. Raise the preliminary examination at once to a good university standard. Let there be no delay and no half-measures. Weed out boldly. By so doing a large proportion of the unfit will be debarred at the very threshold from entering a profession which they are not fitted to adorn. Lessen the crowd of hungry aspirants who now greedily compete for every appointment, be it ever so paltry, and undersell each other like petty tradesfolk for sixpences and shillings, so that the average practitioner may once more have leave to live and to respect himself. When the principal is decently remunerated the assistant will be decently paid and things will right themselves all round. The public, too, will be the gainer, for the whole tone of the profession will be raised, and it will get a better article for its money, though not perhaps quite such a ruinously cheap one. It is vain to agitate for a legally-recognised minimum fee unless the plea be backed by large and solid voting-power, such as the profession has never had nor ever will have at its command. It is also inexpedient, for such a fee would only tend to pauperise further those who can afford to pay something but not much, so that the remedy might prove worse than the disease. At present an easy preliminary examination opens the door to a long curriculum and hard professional examinations. These, in their turn, open the door to a fierce struggle for existence in an overcrowded arena. Thus the socially and intellectually unfit crowd in—to their own discomfiture at the examination tables or to that of their *confrères* in after life.

The General Medical Council has eliminated the unqualified assistant. Let it follow up what it has well begun by eliminating the unqualified qualified man who enters the profession unhampered by the instincts and culture of a gentleman; who brings his calling into contempt and takes the bread from the mouths of his professional brethren by giving advice and medicine for a few pence; who cannot speak his mother-tongue correctly or indite a grammatical letter; and who munificently rewards his duly qualified and registered assistant with a salary about equal to that of a bricklayer's labourer.—I am, Sirs, yours faithfully,

July 23rd, 1898. M.D. EDIN.

A POINT UNDER THE INFECTIOUS DISEASES (NOTIFICATION) ACT.

To the Editors of THE LANCET.

SIRS,—I have recently been attending several members of a family suffering from an infectious disease which I notified to the public health authorities in due course. On their recovery the rooms in which the patients had been were disinfected by burning some chemical substance the nature of which I am not acquainted with, under the supervision of the afore-mentioned public health authorities. At the termination of this a paper was left with my patients for me to sign—a printed document in legal phraseology—stating that the process of disinfection had been carried out to my satisfaction and that all articles in the rooms had been thoroughly and efficiently cleansed and disinfected. It was intimated at the same time by the father of the patients that the authorities had informed him that if his medical practitioner signed this it would save further trouble and expense of stripping walls, papering, perhaps painting, &c., but failing that the above would very likely have to be done, though in their opinion it was not necessary. You observe there is no communication between myself and the authorities, it is all conveyed to me by more or less irresponsible but interested third parties and I have to take their word for what has been done; this document to be signed within twenty-four hours. I endeavoured to keep out of the affair by saying that it was for public health people to do as they thought best, but I was so worried by the family that I eventually signed the required form.

It is needless for me to enter into the very unpleasant position this kind of thing places a general practitioner with his patients. I know it is useless discussing this particular case any further. I have acted as I believe for the best and must take my chance of anything cropping up in the future, but the question is, how should one act another time? It appears to me that the responsibilities which were intended to rest with the administration of the Public Health Act are thus thrown upon the practitioner in attendance, rendering him liable to an action at law if such were at any time contemplated by an aggrieved patient. I will not further encroach upon your valuable time by discussing other matters connected with this affair of less importance which naturally present themselves.—I am, Sirs, yours faithfully,

July 25th, 1898. PUBLIC HEALTH.

*** We think our correspondent's scruples about attaching his signature very reasonable.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Bombay City: The Need for Water-meters, the Rise in the Subsoil Water, and the General Health; Plague in the Presidency.—Calcutta: The System of Licensed Family Hospitals for Plague; Extraordinary Regulations for the Lady Nurses.

IT has been asserted for many years that the subsoil water of Bombay was rising and that the soil was becoming water-logged. This has been attributed to the enormous waste of water. The city of Bombay is well supplied with water from several sources, the total quantity brought into the city being at the rate of between 40 and 50 gallons per head per day. Judging from the supplies to other Indian cities probably 10 gallons would be amply sufficient for all domestic purposes. There are numerous public taps continually left running as well as other sources of waste. This reckless waste is a source of considerable loss to the municipal revenue and the reduction of pressure in the mains is so reduced that the supply of water in case of fire is seriously interfered with. Too much water is in reality brought in by the mains, a large portion of which soaks into the soil and is not carried off by the sewers and surface pipes. The municipal commissioner in a recent report most powerfully shows the necessity of adopting the meter system. The proposal has been drawn up so as to provide liberally for the wants of the people. Considering this question so far as it affects the public health this important observation must be made. Notwithstanding that about 30 inches of rain have already fallen during the present monsoon, the reckless waste of water for many years, and the water-logged condition of the soil, the death-rate from diarrhœa and dysentery is 50 per cent. below the average, fevers are lower than the average of past years, and diseases of the respiratory organs show no increase. It is evident, therefore, that the saturation of the soil by all these causes is not immediately productive of disease, although doubtless, from the experience of drainage improvements in English towns, it has some injurious effect on the total yearly mortality. The deaths for the past week have been at the rate of 26·13 per 1000 per annum.

With regard to plague, it is unsatisfactory to find that while the returns are not so high as last week they are higher than the minimum attained in June. The quarter of Mandvie may almost be looked upon as the centre from which the disease spreads. Nine deaths were registered there during the past week. Plague is still existent in the following districts: Broach, Surat, Thana, Satara, Koluba, Belgaum, Dharwar, and Kathiawar.

A very diplomatic compromise between what ought to be done and the wishes and prejudices of the natives has been effected in Calcutta by the establishment of licensed family hospitals for plague cases. The sanitary measures hitherto adopted elsewhere are not adapted to the Indian people and consequently the regulations about plague have been evaded in every possible way. The establishment of this system, therefore, has gained the confidence of the people. Besides the public hospitals and the ward hospitals there are numerous private hospitals, so that all the communities are now well provided for. In addition to this houses possessing anything like suitable accommodation for the isolation of a case of plague are allowed to have one or more rooms set apart for the purpose. By these concessions every case of plague ought to come under observation. The plague scare has greatly subsided and inoculation is coming slowly into favour among all classes. It is very satisfactory to note that the number of cases of plague still continues very small and that it is daily decreasing.

The regulations issued in Calcutta to govern the conduct of the English lady nurses while off duty are simply monstrous. Girls at a school could hardly have their liberty more restricted. Everything has to be referred to the lady doctor who is acting as matron to the establishment. Judged by the rules she must be severely exacting. "Sisters going out driving are required to let the lady doctor know their destination and their escort (if any); and she is given authority to modify the arrangements made." "Visitors to the sisters must send in their card to the lady doctor." The sisters are only permitted to be out for one evening during a week. In case of sickness the sister is only allowed to have the further advice of one of the senior (!) medical practitioners of Calcutta. "Some public duty may be required from such (personal) servant at the discretion of the lady doctor." Even to afternoon tea no visitors may be invited except with the consent of the lady doctor. "*Ladies* may occasionally be invited to other meals (with the consent of the lady doctor)." These rules are issued, printed, and are signed by R. T. Greer, acting chairman. It will be remembered that the sisters were appointed by the Secretary of State for India and came out from England with the title of lady nurses and that they rank as lady superintendents. They were required to furnish the highest credentials of service and capacity. They are, in fact, an exceptionally well-trained staff. Under these circumstances the indignity offered them by these childish regulations is most offensive. Their agreement does not refer to any rules of conduct—only to the lodging and other accommodation to be provided for them. It is evident, therefore, the authorities have exceeded their powers and have placed the English sisters in a position which must lower the public respect due to them as highly trained nurses. The position of the lady doctor under these circumstances must be a most unenviable one.

July 9th.

THE SOUDAN CAMPAIGN.

(FROM OUR SOUDAN CORRESPONDENT.)

THE general health of the troops up here is excellent although several scattered cases of enteric fever and dysentery have occurred. The men are, of course, rather "fine-drawn," but only to the extent one would expect to

Digitized by Google

find them after a prolonged stay in the frightful heat of the Soudan in the summer months. The general surroundings of the camp as regards sanitary requirements are good; the water-supply is carefully looked after, all used being filtered, and the supply of Pasteur filters is ample, although it is to be regretted that they were not brought into use before. The temperature runs up to anything in the sun, but in the mud huts and tents the average is about 90° F. The nights are fairly cool and pleasant and were it not for the plague of flies which pervade the huts and make writing or reading almost impossible there would be little to complain of. The men get fresh rations of very fair meat and their diet is supplemented by the issue of bacon and jam twice a week. The scarcity of green stuff and vegetables is, of course, sorely felt, but under the circumstances the food is ample, and there is little cause for grumbling even by that prince of grumblers "Thomas Atkins."

We are sorry to hear that after six months' hard work, able organisation, and devotion to the health and comfort of the numerous sick and wounded, our present principal medical officer, Lieutenant-Colonel McNamara, is to be superseded by an officer of higher rank from home, who will come out and find everything in first-rate order (thanks to his predecessor's unremitting attention). The medical arrangements for the advance are nearly complete and there will be no lack of medical officers when the fighting begins. The hooded stretchers are on their way, if not already here, and the Royal Engineers have been turning out a supplementary supply of splints suitable for field work; in fact, field, communication and base hospitals are excellently equipped. Two sets of x rays are on the way out, but their utility in field work remains to be seen, and I cannot fancy they will be of that amount of service which is anticipated by honourable and gallant Members of the House. However, they will be on hand and there are two medical officers, who have been specially trained, available to work them. The hospitals here are to be emptied by the end of the month, and the men who are not likely to stand the wear and tear of the advance will be sent down. The disposition of the medical staff will be: medical officers allotted to each regiment and to field hospitals, hospitals on the lines of communication, and the base hospital at Cairo.

Darmali, Soudan, July 8th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Distribution of the Hospital Sunday and Saturday Fund.

THE following amounts have been allotted from the Hospital Sunday and Saturday Fund:—£2640 to the Liverpool Royal Infirmary; £1800 to the Royal Southern Hospital; £1560 to the Northern Hospital; and £840 to the Stanley Hospital. Other charities also benefit by various smaller amounts out of a total of £12,000 which has been distributed. An effort was made at the meeting of the Distribution Committee to alter the date of the Sunday collection from the second Sunday in January to the second Sunday in March owing to the numerous complaints of the hardships of contributing so soon after Christmas. The secretaries had invited opinions as to the desirability of altering the date by issuing circulars to 292 places of worship contributing to the Fund. 57, representing a contribution of £2174 1*s.* 10*d.*, were in favour of the existing fixture; 114, representing a contribution of £1727 10*s.* 9*d.*, voted for a change to the month of March; 79, representing a contribution of £1799 6*s.* 9*d.*, sent no reply; whilst others were indecisive. The proposed change was opposed by Mr. F. W. Lowndes (to whose efforts were largely due the early introduction of Hospital Sunday in Liverpool), who urged that a change of date would decrease the total of collections. The feeling of the meeting was in favour of retaining the January fixture, with the result of the rejection of the amendment by 10 to 5 votes.

University College, Liverpool: Fellowships.

The Holt Fellowships in Physiology and Pathology established by the late Mr. George Holt in 1886 for a period of ten years and renewed for a further period by Mrs. and Miss Holt have been awarded to the following gentlemen respectively: Mr. A. Hope Simpson, provisionally upon his attaining full qualifications within a period of three months and Mr. K. Nelson. The Robert Gee Fellowship in Anatomy of the value of £100 has been awarded to Mr. F. Lovegrove.

Hospital for Women, Shaw-street.

Dr. Murray Cairns has been appointed to the new post of stipendiary medical officer for a term of six months; the appointment carries with it an honorarium of £50.

Donation to the Chester Infirmary.

Mrs. Auster, of Edgbaston, Birmingham, has given a donation of £1000 to the Chester Infirmary for the endowment of a bed to be called the "Mr. and Mrs. John Churton Memorial Bed."

The Sanitary Condition of Wallasey, &c.

The annual report of Mr. Francis Vacher prepared for the County Council of Cheshire states that the birth-rate for the county, exclusive of Chester, Birkenhead, and Stockport, reaches 27·8 per 1000 living. There were 9810 deaths registered during the year 1897, giving an excess of births over deaths of 6432, the death-rate varying from 25·2 per 1000 at Neston and Parkgate to 11·3 per 1000 at Bowden and 8 per 1000 at Alsager, the average being 16·8 per 1000, against 17·4 per 1000 for the whole of England and Wales. Wallasey, near Liverpool, is spoken of with approbation as regards the percentage of successful vaccinations. On the other hand, typhoid fever was exceptionally prevalent there in 1897. In a house where a fatal case of typhoid fever occurred the roof of a very offensive privy was formed by the floor of a sleeping apartment. In another house visited by typhoid fever the soil-pipe was inside the house, the flushing-pipe of the water-closet was connected with the house system and the sink waste-pipe was connected to the drains. In a cottage in Wood-lane, Wallasey, it was found that a mother, four sons, of from seventeen to twenty-three years of age, and a daughter aged fourteen years, were sleeping in the same apartment. Some parts of Wallasey clearly stand in need of the vigilant attention of the officials of its health department.

July 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medico-Psychological Association.

THE fifty-seventh annual meeting of the Medico-Psychological Association of Great Britain and Ireland was opened in Edinburgh on July 21st. After the transaction of routine business the retiring President, Dr. T. W. McDowall, of the Northumberland County Asylum at Morpeth, introduced the President-elect, Dr. A. R. Urquhart, of James Murray's Royal Asylum, Perth, who in the preliminary portion of his presidential address touched on the improvements which had taken place in the treatment of insanity, illustrating his remarks by examples drawn from the history of Murray's Asylum. He then said that three Bills before the present Parliament were of special interest to the members of the association—namely, the English Lunacy Bill, the Habitual Drunkards Bill, and the Irish Local Government Bill. With respect to the first he regretted that it contained no proposal for increasing the number of the Commissioners in Lunacy, and he expressed a fear that its policy of legal restraints constituted a danger, for if the treatment of lunacy was governed by a department of the State the effect would be to fetter originality by the red-tape of bureaucratic control and to trammel the advance of scientific opinion by the deadweight of that officialism which is the besetting sin of asylum life. He congratulated his colleagues in Ireland on their opposition to the proposal to transfer the care of the insane to the Local Government Board and on their suggestions for the more efficient medical service of the Irish asylums. He particularly objected to the proposals in the Lunacy Bill to set apart the various wards of an asylum for certain specific purposes and to the limitation of the uses of succursal villas. With regard to the Habitual Drunkards Bill he thought that it ought to provide exceptional protection for individuals so handicapped in life's race and that the courts of law should be empowered to sequestrate any man who has so lost control of himself as to be a danger to himself and others by reason of his indulgence in intoxicants.

University of Glasgow.

The summer graduation ceremony was held on July 21st. Sir William Gairdner, K.C.B., presided and in the name of the Senate conferred the degrees on the various graduates, the great majority of whom belonged to the Faculty of Medicine. Thirteen gentlemen received the degree of M.D., Mr. J. W. Findlay, M.B., C.M., gaining honours for his thesis on the Choroid Plexus of the Lateral Ventricles: their Anatomy, Functions, and Pathology in Relation especially to Insanity. Mr. R. Gordon Bell, M.B., C.M., and Mr. J. D. O. Wilson, M.B., C.M., were commended for their graduation theses. Nine gentlemen graduated M.B. and C.M. under the old regulations and fifty-four graduates under the new regulations were "capped" M.B. and Ch.B. Amongst these Mr. William K. Hutton, M.A., Mr. Robert Fullarton, M.A., and Mr. William Webster were awarded "Honours," the first-named also gaining the Brunton Memorial Prize as the most distinguished graduate of the year. There were nine lady graduates. The customary address was delivered by Professor Stockman, who expressed in graceful terms his congratulations to the newly made graduates and gave them some sound advice in reference to their professional bearing and conduct. Passing from these appropriate though possibly somewhat trite topics Professor Stockman proceeded to attack in very energetic terms the conditions and circumstances attached to the chair which he occupies in the University. He found himself, he said, without a single scientific instrument either for teaching or research purposes, without any laboratory, and without any hospital wards where he could acquire experience in the actions of medicines, and where clinical instruction could be given to the students who were dependent on him for such instruction. If the present state of matters is to continue Professor Stockman pronounced that his teaching must necessarily become obsolete and he himself an incubus upon the University. These are certainly somewhat startling statements and have excited much comment both in professional and lay circles. As far as is known it is the first complaint that Professor Stockman has made of the equipment of his chair and it is not therefore surprising to find that the course he has chosen to pursue is sharply called in question. A public proclamation of inefficiency will scarcely be grateful to the University authorities nor will it advance the reputation of Glasgow as a medical centre, whilst the selection for the reception of such a complaint of an audience the vast majority of whom were taught by the former occupant of the chair may be criticised on the score of taste, other matters apart. However, there will be a general wish that the outcome will be an improvement in the laboratory and practical equipment of Professor Stockman's chair.

University of St. Andrews.

The following appointments have been made by the University Court: Alexander Mitchell Stalker, M.D. Edin., physician to the Royal Infirmary, Dundee, to be Professor of Medicine; David MacEwan, M.D. Edin., surgeon to the same infirmary, to be Professor of Surgery; and Charles Templeman, M.D. Edin., to be Lecturer on Forensic Medicine and Public Health in University College, Dundee; and David Fraser Harris, B.Sc. Lond., M.B. Glasg., F.R.S. Edin., to be Lecturer on Physiology at St. Andrews.

The Workmen's Compensation Act: Appointment of Medical Referees.

The Secretary for Scotland has appointed the following gentlemen as medical referees for Lanarkshire under the Workmen's Compensation Act, 1897: Dr. Hector Cameron, 200, Bath-street, Glasgow; Dr. T. K. Dalziel, 196, Bath-street, Glasgow; Dr. G. T. Beatson, 7, Woodside-crescent, Glasgow; Dr. Duncan Macartney, 18, Newton-place, Glasgow; Dr. James C. Renton, 1, Woodside-terrace, Glasgow; Mr. H. E. Clark, 24, India-street, Glasgow; Dr. David Newman, 18, Woodside-place, Glasgow; Dr. W. J. Fleming, 3, Woodside-terrace, Glasgow; Dr. James Barras, Westbourne, Bellahouston, Govan; and Dr. Hugh Arthur, Fruitfield, Airdrie. These gentlemen act according to a rotation to be fixed by the sheriff, which will in all probability be according to the above order.

The Sheriff-Clerk of Paisley has received intimation from Sheriff Sir John Cheyne that the Secretary of State for Scotland has appointed the following gentlemen as medical referees under the Workmen's Compensation Act, 1897:—Dr. Donald Fraser and Dr. Thomas Graham for the burgh of Paisley; Dr. James Whiteford and Dr. Thomas Philip for the burgh of Greenock; Mr. R. H. Parrie, 72, Queen's-drive, Glasgow, and Dr. A. E. Maylard, 10, Blythswood-square, Glasgow, for the county of Renfrew outwith the burghs of Paisley and Greenock; Dr. Robert Allan, Ardrossan, for Arran, in the county of Bute; and Dr. J. N. Marshall for the county of Bute, excepting Arran.

Sudden Death of the Medical Officer of Montrose.

On Friday, July 22nd, there died suddenly at Montrose Mr. Herbert William Greatbatch, M.B., C.M. Edin., who was appointed medical officer of the borough of Montrose a few months ago. After graduating he was for two years a junior medical officer at Sunnyside Asylum, near Montrose, and thereafter he was assistant to Sir J. Batty Tuke of Saughton Hall Asylum, Edinburgh. After two years' practice on his own account in Staffordshire, during which period he was deputy medical officer of health in the borough of Stoke-upon-Trent, he returned to Montrose in 1895 and entered into partnership with Dr. Andrew Key, the oldest medical man in the town.

Aberdeen Sick Children's Hospital Bazaar.

H.R.H. Princess Henry of Battenberg has agreed to open the bazaar to be held in Aberdeen on Oct. 28th next in aid of the Royal Aberdeen Hospital for Sick Children. The number of patients in the wards on July 21st was 80 and at Eidda Home 11; total 91.

July 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Public Health Congress in Dublin.

HIS EXCELLENCY THE LORD LIEUTENANT has consented to formally open the Health Exhibition in connexion with the Congress in the Royal University Buildings on Aug. 18th at 3 o'clock. A meeting of the Executive Committee of the Congress was held on July 20th at the offices of the Public Health Department, Dr. Thomas W. Grimshaw, C.B., Registrar-General, occupying the chair. A meeting of the committee of the municipal and Parliamentary section in connexion with the above was also held on the same day, under the chairmanship of Alderman the Right Hon. J. M. Meade, P.C., LL.D., when the details of the programme as affecting the section, together with the subjects for discussion, the titles of papers proposed to be read, &c., were carefully considered. Sir William Stokes has accepted the office of Vice-President of the section of Preventive Medicine and Vital Statistics.

The Proposed Division of the Richmond Asylum District.

At the last meeting of the governors of the Richmond Asylum, held on July 14th, an important letter was read from the Inspectors of Lunatics in Ireland with regard to the probable number of patients who will require accommodation in the near future and the advisability of dividing the district. The communication pointed out that the number of patients in the asylum amounted to 1945. The number of the insane in workhouses in the city and county of Dublin, the county of Wicklow, the county of Louth, and the town of Drogheda on Dec. 31st last was 644; the number wandering abroad, according to the census of 1891, was 312, making a total of 2901. The Inspectors stated that under those circumstances they had laid before the Government the question of dividing the Richmond Asylum District.

The Royal Victoria Hospital, Belfast.

A meeting of the subscribers of this hospital was held in Belfast on July 20th to consider the proposed charter which has already been approved by the Board of Management of the Royal Hospital.[1] On the motion of the chairman (the Right Hon. W. J. Pirrie, High Sheriff of Antrim), seconded by Mr. W. H. Dixon, chairman of the Board of Management of the Royal Hospital, the amended charter as submitted was adopted. Special votes of thanks were passed to the corporation of Belfast for so kindly granting a site for the new hospital and for obtaining the sanction of Parliament. The site given by the corporation is worth from £30,000 to £40,000 and it enables the committee to devote the whole of the £100,000 to the cost of erection. Thanks were also given to the Right Hon. W. J.

[1] THE LANCET, July 16th, 1898, p. 177.

Digitized by Google

and Mrs. Pirrie for their exertions on behalf of the hospital scheme. It was announced that there was a sum of £64,000 in the bank to the credit of the fund and there was also a considerable amount promised towards an endowment scheme.

Typhoid Fever and Shellfish.

At a meeting of the Public Health Committee of the Belfast Corporation, held on July 21st, Dr. Bigger, physician to the Fever Hospital, called attention to the fact that many cases of typhoid fever had been traced to the eating of shellfish gathered on the odoriferous banks of Belfast Lough, which are saturated with sewage matter, and it was decided to call public attention to this circumstance in order that people may be apprised of the danger of eating shellfish taken from such an unsavoury locality. It is a great misfortune that both sides of Belfast Lough for a considerable distance from the city, owing to the deposit of sewage matter, &c., in the seaweed at low tide, emit the most horrible stench, especially in the present unusually hot and dry weather.

The Londonderry Lunatic Asylum.

It would seem that the Grand Jury of the county of Londonderry has passed a resolution by 19 to 14 urging that, pending the coming into office of the county council, the Board of Control be requested to restrain the governors of the lunatic asylum from taking further action towards the proposed building scheme, as reported in THE LANCET.[2] Sir Thomas Lea, Bart., M.P., is to ask a question in the House of Commons in reference to this undoubted difference of opinion in county Derry as to whether a moribund body has the right to incur such an expenditure of money so shortly before the transfer of its powers to the county councils.

The Workmen's Compensation Act.

Dr. J. Walton Browne and Dr. T. Sinclair Kirk have been appointed medical referees under the new Workmen's Compensatton Act.

July 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Notification of Infectious Diseases.

AT the meeting of the Academy of Medicine held on July 19th M. Monod said that the notification of infectious diseases was an excellent measure and that the notifications had risen from 23,414 in 1896 to 26,000 in 1897. The authorities had done all in their power to obtain notification by medical men; prosecutions were only undertaken when failure to notify involved danger to the public—as, for instance, during an epidemic. M. Ferrand, who was not an advocate of the system, having compared it to the declaration of births and having expressed the opinion that the onus ought to be laid on the family, M. Monod replied that this change would be difficult to make, for, apart from medical men and some exceptionally well-informed persons, people generally believed that there was some objection to their notifying cases, and it would be remembered that certain parochial authorities had acted as if they shared this opinion. However, the Public Health Bill which was being prepared would extend the duty of notification to heads of families, hotel-keepers, and persons in attendance on the patient.

Pathology of Caseous Pneumonia.

At the same meeting of the Academy of Medicine M. Grancher read for M. Auclair a paper in which he sought to show as the result of numerous experiments that caseous pneumonia is due exclusively to toxins elaborated by Koch's bacillus. All authors have regarded it as a mixed infection due to streptococci and pneumococci. If extracts of cultures of the tubercle bacillus made with ether or chloroform are injected into the trachea of guinea-pigs the result will be the production of caseous pneumonia with giant cells, fibrinous exudation, sclerosis, &c. Cultivation experiments made with the caseous foci thus obtained never yield cultures. Nothing can be more decisive as to the connexion of caseous pneumonia and tuberculosis.

Regeneration of the Mucous Membranes.

At the same meeting of the Academy of Medicine M. Cornil stated that he had recently been studying the repair of mucous membranes and that he had ascertained several new facts by experiments made in dogs on the urinary bladder, the gall-bladder, the uterine mucous membrane, and the ureter. The regeneration of the uterine mucous membrane is accomplished by means of the glands in a peculiar way. The method of investigation consisted in slitting up the ureter or the uterine horn longitudinally and killing the animal some hours or days afterwards. He found in the course of his experiments that mucous membrane, that of the ureter for instance, might be grafted directly on the omentum. The facts brought to light by M. Cornil are of great importance from the point of view of general anatomy.

The Artichoke as a Culture Medium in Micro-biology.

Bacterial cultures have been made on almost all vegetables, but the potato and the carrot are the principal ones which are in daily use in bacteriology. M. Roger has, however, reported to the Society of Biology, at the meeting held on July 16th, that in his opinion the artichoke possesses several advantageous qualities in this respect. Nothing is more simple than to prepare it for the purpose. After having stripped off the scales the thick part is cut up into little cubes, care being taken to preserve the fibres *(foin)*. The pieces are placed in tubes plugged with damp wadding, the fibres being uppermost, so that the culture medium is represented by a fleshy mass surmounted by a sort of tuft. When the wadding is inserted the whole is heated in an oven to 115° C. for a quarter of an hour. In making the inoculation the germs must be deposited at the point of insertion of the flowers.

Influence of Tuberculin on Cultures of Koch's Bacillus.

At the same meeting of the Society of Biology M. Carnot mentioned that he had ascertained that if a small quantity of liquid derived from a previous culture of Koch's bacillus is added to the ordinary culture media before they are inoculated with tuberculous material the effect is to hasten the growth considerably. In practice the same result is obtained by adding some drops of tuberculin to the culture media. If, on the contrary, the quantity of tuberculin is increased—if, for instance thirty drops are added to a culture instead of five or six—the culture either does not undergo development or else its development soon stops.

Rabies in Dogs.

The general report presented by Professor Proust to the Council of Hygiene on the cases of rabies observed in 1897 in the department of the Seine elicited from that learned assembly numerous interesting remarks on rabies and its treatment. Finally, the council repeated the two resolutions which it passes every year: 1. That the council approves of the regulation of May 30th, 1892, relative to stray dogs and recommends that this regulation should be strictly enforced throughout the jurisdiction of the prefect of police. 2. That the council urges the authorities to prosecute the owners of animals which have shown themselves to be vicious and with regard to which the police have presented reports.

July 25th.

MR. D. M. FORBES, who for the last thirty years has held the office of medical superintendent of the Infirmary of St. Leonard's, Shoreditch, was on July 19th entertained to luncheon at the Holborn Restaurant and presented with a testimonial on the occasion of his retiring from that position. Mr. R. G. Alabaster occupied the chair and the company included many of Mr. Forbes's personal friends, among the number being the Ven. Archdeacon Sinclair and a few medical men. Mr. Forbes, a Scotsman by birth, has for many years been a prominent member of the Royal Scottish Corporation and the Royal Caledonian Asylum, and a generous contributor to the funds of these charitable institutions as well as a warm supporter of other Scottish societies in London. He did excellent work with regard to the better treatment and nursing of the sick in the Poor-law establishments of this country and the passing of the White Lead Factories Act of 1891 which has done much to ameliorate the condition of the workers in that industry. The testimonial took the form of a beautifully illuminated address on vellum, together with a purse containing over 600 guineas.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT EDINBURGH.

THE sixty-sixth annual meeting of the British Medical Association was opened at Edinburgh on Tuesday, July 26th, under the presidency of Sir THOMAS GRAINGER STEWART, M.D., LL.D., F.R.S. Edin., Professor of Medicine in the University of Edinburgh and Physician-in-Ordinary to Her Majesty the Queen in Scotland.

The Association first met in Edinburgh in 1858, under the presidency of the late Dr. William Pulteney Allison; its next visit was in 1875, when the late Sir Robert Christison was President. It is therefore twenty-three years since the Association last met in Edinburgh and the selection of the capital of North Britain for a meeting was to make it a foregone conclusion that the gathering would be a successful one. For not only is Edinburgh a city which is beautiful by situation and architecture, but she is endeared to every medical man by the splendid traditions of her medical school and the memories of Simpson, Syme, and countless other masters of our science whom we leave unnamed because no attempt can here be made to write a roll call of Edinburgh's medical heroes. It is no wonder, therefore, that an unusual number of members are attending and that the contingent of foreign guests should be particularly large.

The arrangements for the reception of members and guests during the week have been excellent. The reception room has been taxed to its utmost capacity to accommodate the large number of members who have assembled each morning to procure the daily journal and to seek information on various matters. This was especially the case on Tuesday morning, when very many members were registering their arrival, and the crowded state of the room must have caused the officials not a little anxiety in their endeavours to satisfy the needs of the large numbers patiently waiting for attention. But for this successful organisation great thanks are due to the general secretaries of the local committees, Dr. R. W. Philip and Dr. J. Shaw M'Laren, as well as to the secretaries of each committee. The hardest work would naturally fall upon the secretary of the Entertainments Committee and the duties of the post were admirably discharged by Dr. A. Stodart-Walker.

A most convenient feature of this year's gathering was the location of the sections in the University New Buildings, which afforded ample shelter for all sixteen sections under one roof—an accommodation which the Association is not often able to avail itself of or many places to offer. The great advantage thus presented to those desirous of attending more than one section the same morning does not need any emphasising. As a rule at congresses much valuable time is spent and much temper is lost in getting about from section to section, but all this has been avoided at the Edinburgh meeting of the British Medical Association.

An opening service was held in St. Giles's Cathedral at 11 A.M. on Tuesday for the members of the Association. Dr. Whyte, Moderator of the Free Church General Assembly, delivered the address and founded his discourse on the text, "The greatest of these is charity," exemplifying it by tracing the life and work of Sir Thomas Browne, the author of the "Religio Medici," and declaring that if ever any man was a truly Catholic Christian it was he. The collection was, as usual, for the Royal Medical Benevolent College and the British Medical Benevolent Fund.

The Drill Hall in Forrest-road, the entrance to which is almost exactly opposite the reception-room, proved to afford quite adequate space for the exhibition of drugs, foods, and sanitary and surgical appliances which is usually associated with the annual meeting of the Association. Although the exhibition was announced to be opened on Tuesday there was very little sign of the arrangements being completed on the morning of that day. By the afternoon, however, the scene had considerably changed and had rapidly assumed the appearance of a really attractive and artistic show. The arrangements were well planned and while the allotted spaces were individually sufficient from the point of view of the exhibitor, there was yet plenty of room for the visitors to move about freely. Indeed, the thoroughfares dividing the lines of stalls made the visit of inspection comfortable and afforded the visitor some chance of appreciating the taste displayed by the exhibitor in his exhibit. A fairly large proportion of the space was taken up by local firms, several well-known chemists and druggists of Edinburgh exhibiting their fine pharmaceutical products and specialities. A feature of the exhibition was the sanitary section, in which were displayed hospital appliances and furniture, models of aseptic operating rooms, &c., included with which was a working model of the septic tank system of sewage treatment. The attendance was good and encouraging to those concerned. We propose to deal at some length with this interesting section in a special article by our commissioner in which the whole of the exhibits will be properly classified, the first section—viz., drugs—appearing in our present issue.

A meeting of the Hospital Reform Association, under the presidency of Dr. Ward Cousins, was held on Tuesday morning. Several papers were read, one of which suggested that a certain number of medical practitioners should be appointed on the executive committees of all medical charities. In that way lay philanthropists who had hitherto pulled the strings of the hospitals with no distinguished success would be kept in touch with the views of the profession. Dr. Rice, of Coventry, described the various attempts which had been made to induce the staff of a badly conducted local dispensary to resign their posts. Those gentlemen, however, not only defied their brethren but also the clearly expressed condemnation of THE LANCET and the *British Medical Journal*. Another speaker stated that one of the Irish colleges had taken action with regard to a diplomate who dealt with a "middleman" to the discredit of his cloth. One of the English colleges, he added, had definitely promised to inquire into the case of any member if clear evidence were forthcoming that he belonged to an association which touted for membership. Several Glasgow practitioners stated that considerable abuse of hospitals went on in their town. The honorary staffs were practically powerless to refuse treatment to applicants unworthy of charitable relief. The system of hospital letters enabled a subscriber of one guinea to demand three guineas' worth of hospital in-patient relief. One speaker gave a specific instance of a patient of his own whose personalty ran into five figures and from whose executors he was paid an account of three figures, but who nevertheless died in a hospital. The President emphasised the fact that the hospital staff had great power in their hands by refusing to treat unfit cases, and that the Reform Association was simply the friendly critic, not the enemy, of the hospital system. The work of this body, moreover, was intended to supplement, and in no sense to replace, that undertaken by the

Digitized by Google

Charities' Sub-committee of the British Medical Association. The secretary, Mr. Garrett Horder, read a short paper on The Dispensary System in Scotland where he concluded that abuses existed just as they did in England. He pointed out the successes achieved by the Association in the past and was hopeful of far greater results in the near future. The figures giving the numbers of patients of medical charities for 1897 in the eight principal Scottish towns are worthy the serious attention of the medical profession.

The Museum of Science and Art was the scene of a successful reception on Tuesday evening, when the Lord Provost of Edinburgh and Mrs. Mitchell Tompson were at home to the Association. The Provost, in his official robes, was attended by the Sword and Mace and a number of the city officials; and among those present, apart from the members of the Association were Lord Strathcona and Mount Royal, Sir Charles Cameron, M.P., Dr. Farquharson, M.P., and Mr. J. G. Weir, M.P. Some 4000 ladies and gentlemen accepted the Lord Provost's hospitality.

The Anglo-American Continental Medical Society, whose object is "to serve as a bond of union between the British and American practitioners established on the Continent of Europe and Northern Africa," gave a luncheon at the Balmoral Hotel on Wednesday. Sir William Turner, who occupied the chair, gave the toast of "The Queen and the President of the United States," and said that the first part of his toast appealed to those of the nationality implied in the word "Anglo," meaning the inhabitants of the United Kingdom, and he would therefore give the toast of "The Queen." This having been duly honoured Sir William Turner remarked that the second part of the title was the word "American," and that in saying this they must all think of the President of the United States, who was at present engaged in a struggle more difficult than any encountered by his predecessors since the days of Lincoln. The Chairman next proposed the "Health of the Society," coupling with it the name of Dr. Miller, of Paris, who briefly replied. Dr. Sandwith, of Cairo, proposed the "Health of the Guests," coupling with it the names of Dr. Condé, of Paris; Professor Baginsky, of Berlin; Dr. H. Curtis, of New York; Mr. Bryant, and Dr. Frederick Roberts. Dr. Condé, in reply, made a happy little speech in French and Professor Baginsky, speaking in English, referred to the friendly sentiments which really existed between England and Germany, though they were sometimes obscured. Dr. Brock, of Rome, proposed the "Health of the Chairman," who replied, and the proceedings terminated.

The election of the Earl of Aberdeen, the retiring Governor-General of Canada, and of Lord Strathcona and Mount Royal the High Commissioner, as honorary members of the Association, was a graceful recognition of the services rendered by them to the Association at its meeting in Montreal last year.

At the special invitation of the Livingstone Medical Missionary Society the collection of medical and surgical antiquities from Pompeii and Rome were placed at the disposal of the authorities in Heriot's Hospital by Messrs. Oppenheimer and Co., and excited considerable interest. The collection was substantially the same as that exhibited in the Savoy Hotel on the occasion of the meeting of the Association in London in 1895.

The breakfast at the Edinburgh Café under the auspices of the British Medical Temperance Association was well attended. Professor Simpson occupied the chair. The annual report showed that satisfactory progress was being made by the society, the increase in the number of student-associates being noteworthy. The President, Dr. G. Sims Woodhead, said he had been accused of having asserted that alcohol as a drug was absolutely of no use. What he had asserted was that if alcohol was a drug it must be treated as a drug. Dr. Clouston said the first mental effect of alcohol was to diminish the power of control, and in his opinion no man should take alcohol before his beard had grown. Dr. Ridge (the honorary secretary), Dr. Connell of Peebles, and Dr. Young also spoke.

On Wednesday afternoon a garden-party was given to the members of the Association at Craig House by special invitation of the managers of the Royal Asylum, the guests being received by Sir Alexander Christison and Dr. Clouston. On the same afternoon parties were given by Mrs. Ford at Dreghorn Castle and Mrs. Nelson at Salisbury Green. Receptions were also held by the Public Health Committee of the Corporation of Edinburgh, by the Scottish Society of Painters in Watercolours, and by the Town and Gown Association. In the evening a soirée was given by the President and local committee of the Association in the McEwan Hall and New University Quadrangle.

On Thursday afternoon Professor Annandale delivered the Address in Surgery at the third general meeting. Receptions were held by the Senatus Academicus of the University of Edinburgh the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Medical Society. A garden-party was given at Inverleith House by Professor and Mrs. Bayley Balfour. In the evening the annual dinner of the Association was held in the Music-hall, George-street.

THE selection of Portsmouth as the place for the next annual meeting of the Association is a fitting response to the invitation more than once extended to the Council by the practitioners of that important city. Dr. Ward Cousins's work for the Association has earned him the presidency and we congratulate him upon it.

THE GENERAL MEETINGS.

THE FIRST GENERAL MEETING.

The first general meeting of the Association was held in the McEwan Hall of the New University Buildings at 2.30 P.M. on Tuesday, July 26th. Previously to the opening of the proceedings Mr. Collinson, organist of St. Mary's Cathedral, gave a recital on the magnificent organ. At 2.35 the members of the Council, headed by the Corporation of Edinburgh in their scarlet gowns, with the City Marshal and the Town Clerk, entered the Hall. The Lord Provost, with the Mace and Sword Bearers, and Dr. Roddick, President of the Association for 1897–1898, brought up the rear, while the organist played the march from the *Occasional Oratorio*.

Dr. RODDICK proposed that the minutes of the last meeting should be taken as read, which being agreed to they were confirmed and signed. Dr. Roddick next said that it became his very pleasant duty to resign the Presidential chair in favour of Sir Thomas Grainger Stewart. No introduction of the new President for the coming year was needed by the citizens of Edinburgh or the profession or any country. "In Canada, my own country," continued Dr. Roddick, "his name is a household word, for he has had to do directly or indirectly with the training of most of the more eminent medical men in the Dominion." Dr. Roddick then proffered his warmest thanks to the Association in general, to Dr. Robert Saundby, President of the Council, and to Mr. Francis Fowke, the general secretary, for their kindness and able assistance to him during his term of office.

Sir THOMAS GRAINGER STEWART then took the chair and at once called upon the Lord Provost, Mr. MITCHELL THOMSON, to address the meeting.

Digitized by Google

The LORD PROVOST said it was his very pleasant duty, on behalf of the municipality and citizens of Edinburgh, to offer a very hearty welcome to the members of the British Medical Association. No one would accuse him of speaking in any boasting spirit were he to say that the Association could not have chosen a better place for its deliberations than the ancient city of Edinburgh; for to say nothing of its historical associations it possessed one of the foremost medical schools in the world. Referring to the share which the town council possessed in the patronage of the University chairs he said that the distinctions which Edinburgh had won showed that the council had exercised its patronage with judgment. Sir William Turner, a man deservedly honoured in Edinburgh, had lately been called to the proud position of President of the General Medical Council and only the other day he (the Lord Provost) had had the honour of conferring the freedom of the city upon Lord Lister. It was gratifying to know that their new President was one so well known and honoured as Sir Thomas Grainger Stewart. In conclusion, he would beg to ask members of the Association that they would not allow too strict an attention to business and scientific work to interfere with their enjoyment of the various social functions which had been organised for their entertainment, for it was the desire of the whole city to make their stay as pleasant as possible.

The PRESIDENT then warmly thanked the Lord Provost and the Corporation for their welcome and proposed a vote of thanks to Dr. Roddick and that he should be elected a Vice-President for life.

This was carried unanimously, and Dr. RODDICK in returning thanks mentioned that many other places in Canada, even far distant Victoria, were ready to receive the Association with open arms.

The Lord Provost and the Corporation then retired.

The consideration of the report was then proceeded with and the following recommendation of the Council with regard to the election of new honorary members was unanimously adopted:—

At the meeting of the Association at Montreal no one contributed more to its success than His Excellency the Governor-General the Earl of Aberdeen and the Right Hon. the High Commissioner for Canada, the Lord Strathcona and Mount Royal. At the request of that meeting and in hearty concurrence with it the Council desires to recommend them to you for election as honorary members, in accordance with By-law 6, and considers that by so doing you will honour the Association even more than you honour them. The Council also recommends the election of Professor Francesco Durante, the eminent Italian surgeon, as an honorary member of the Association.

The PRESIDENT then handed the roll of membership to Lord Strathcona, who was present, remarking that Canada seemed destined to be firmly associated with medicine. Sir Charles Tupper, a late High Commissioner for the Dominion, had given up medicine to become a politician, and now they had a distinguished Canadian politician and the present High Commissioner becoming a doctor.

Lord STRATHCONA briefly returned thanks.

Dr. SAUNDBY then moved the adoption of the report. He referred to the increase in membership of the Association (1473 for the past year), to there being a surplus of over £3000, and to the successful negotiations for the purchase of the freehold of the premises in the Strand, Agar-street, and Harvey's-buildings. The death of Mr. Ernest Hart had been a great loss to the Association and especially to the *British Medical Journal*, but he felt sure that Dr. Dawson Williams would prove to be an able successor. With regard to the question of medical defence the result of the postcard plebiscite was that only one-third of the members had answered in the affirmative and so in the words of the report—

Your Council is of opinion that the affirmative majority constitutes too small a proportion (one-third) of the whole Association to justify further steps being taken in a matter so seriously affecting the organisation and working of the Association and respecting which such grave differences of opinion are known to be entertained.

Dr. J. MYRTLE (Harrogate) then moved as an amendment:—

That the question of undertaking medical defence by the British Medical Association having been decided by a majority in favour at the annual general meetings in London, 1895, Carlisle, 1896, and London, 1897, the Council should undertake to reconsider the report, with a view of bringing this great question to a satisfactory issue.

This was seconded by Mr. GEORGE JACKSON (Plymouth).

Mr. VICTOR HORSLEY pointed out that although postcards were sent to every member it was well known that should the Council take up the question it was only intended to apply to the United Kingdom. Now of members in the United Kingdom 60 per cent. answered in the affirmative. He was quite aware that the profession was sadly in need of being waked up, and the Council ought to have subsidised the Medical Defence Union to do this.

Dr. J. HUDSON said that the Association should stick to what it was originally founded for—namely, the advancement of science.

Dr. WARD COUSINS said that the question of subsidising involved a quantity of difficulties.

Dr. WOODCOCK said that he had reluctantly come to the conclusion that for the Association in its present state of division on the question to take up the matter would result in hopeless failure.

Mr. GARRETT HORDER said there was no doubt a very strong desire among the profession that the Association should take up the question, and

Dr. MUIR (Glasgow) said that in his branch only 3 members voted against this proposal and they were all consultants.

On Dr. MYRTLE'S amendment being put to the meeting 101 voted against it and 89 for it.

The amendment was thus negatived by 12 votes, but the members of Council present naturally voted in the majority and they numbered quite 12.

The report was then adopted, after which the reports of committee were considered, and the meeting shortly afterwards adjourned.

THE (ADJOURNED) FIRST GENERAL MEETING.

The adjourned meeting met again on Tuesday evening at 8.30, at the McEwan Hall, to hear Sir Thomas Grainger Stewart's Presidential address.

PRESIDENT'S ADDRESS.

Sir THOMAS GRAINGER STEWART commenced by a few hearty words welcoming the Association to Edinburgh and pointing out how necessary it was that a common understanding should exist between the medical profession and the public as to the position of medicine. He then continued:—

The prevention of disease is in its practical results perhaps the most important of all our duties. It is our chief glory that we have been able to accomplish so much. It is our highest hope that we shall accomplish more. The several members of the great group of diseases which owe their origin to invasion by pathogenic micro-organisms are in course of being rationally explained and so it is becoming possible for us to take measures for their prevention. In some of them we can prevent the development of the organisms. In some we may hinder their multiplication and spread. In some we can block the channels by which they have been accustomed to find entrance into the body. In some we are able to modify the germ so that it produces when inoculated a milder disease and yet a disease capable of conferring immunity against the malady in its ordinary form. In some we can interfere with the action of the germ even after it has been introduced or counteract the poisonous substances which the germs generate. With regard to the important group of diseases due to faulty chemical processes we have learned much that is of service for prevention. We have traced the origin of some diseases to the subtle action of chemical substances introduced with the food or in the exercise of various trades and crafts. We have learned not a little regarding toxic substances which are developed within the body from faulty chemical processes or which accumulate as a result of deficient elimination. And most recently of all we have traced important diseases to deficient or excessive supply of what we have come to know as internal secretions; and each discovery which renders the causation of a disease more clear contributes something towards its prevention. Every member of the profession ought to be keeping his eyes open to the advances of science, for in that he may find explanations of morbid action as Lord Lister did in regard to wounds and ought to be always seeking for an explanation of the occurrence of disease, and especially of epidemic outbreaks, for by watchfulness in such matters mighty results may be achieved, as the work of such men as Snow and Budd and Koch has shown. The public may in many ways benefit from such discoveries and the precautions they suggest. Individual health, family

Digitized by Google

health, social health, and national health, may all be improved if the individual, the head of the family, the employer of labour, and the legislator duly study and act upon these lessons. It is their duty to do so. But an intelligent appreciation of these subjects is not easily attained. Perhaps we are ourselves in some measure to blame for this because our professional customs do not readily lend themselves to the issuing of clear and popular statements by leaders of medical opinion in such forms as would enable the public to share our knowledge. We ought to take more pains to instruct the public in such questions. Individual members of the community should seek to understand how their own personal health and that of their families may be protected when they act according to the light of modern science. Employers of labour should modify the conditions of their work, as, indeed, so many of them do, with the view of warding off the special dangers proper to each occupation. Teachers and governors of schools should study zealously all that we are learning with regard to the evils of deficient ventilation, of cramped attitudes, and of excessive or too prolonged mental effort. In unnumbered ways may intelligent and well-instructed men ward off dangers by attending to the hygienic rules of modern science. But apart from all the private applications of hygienic laws rises the question of the duty which the legislature owes to the facts of medicine. It is an interesting question whether under our democratic constitution we are in a better or worse situation in this matter than we might have been under an absolute monarchy or an oligarchy. It was perhaps easier in the old days when a monarch was absolute to get him to understand medical questions; a Linacre enjoying the confidence of a Henry VIII. or a Harvey that of a Charles could command a sympathetic appreciation of facts which might readily result in valuable Royal edicts. One can conceive that had supreme power been vested in the hands of such a man as the late Prince Consort his fine perception of scientific facts would have led to his being the friend of such men as Chadwick, Farr, Parkes, and Richardson, and that at their suggestion effect would have been given to every legislative advance that medicine justified. And even in oligarchic days one can understand how a group of men wielding the whole power of the State might similarly be convinced and might promptly bring into action legislative machinery for the prevention of disease. But now when every man is a king, when the whole people rule, it is perhaps not so easy to attain the results which we desire. The whole community requires to be instructed before the lessons can be used to good purpose. It is our task to give that instruction; it is theirs to give effect to what we have taught. The country has since the Queen's reign began awakened to the benefits which legislation in medical matters may afford and history will recognise the fact as one of the chief glories of the Victorian era.

Progress in Medicine and the Position of Vaccination.

But I wish that our progress were more satisfactory. Take, for example, the great subject of the prevention of small-pox. With scarcely a dissentient voice the medical profession recognises the transcendent value of vaccination. A Royal Commission laboured for many years and at last reported unequivocally in favour of that treatment. But with a determination which would be admirable if it were not so disastrous a comparatively small group of men set themselves to opposing and maligning the process, belittling its advantages and magnifying and multiplying the slight risks which attend it. To these a considerable section of the English public have given heed rather than to the medical profession — I speak advisedly of English public for, as Mr. Balfour has pointed out, the public of Scotland remains loyal to medical opinion. But from the attitude of certain districts in England it comes about that the greatest discovery in practical medicine, although it had its native home in Britain, is less efficiently carried out here than it is in many parts of the Continent. In Germany small-pox has practically disappeared; there has been no death from it in the whole of the vast German army since revaccination was made compulsory. In 1853 and 1867 Acts were passed for compulsory vaccination in England. These Acts have been the constant object of attack by the anti-vaccination propaganda. The Vaccination Commission was a result of these attacks. It included active opponents and active supporters of the process, with some members who were understood to take up the inquiry without any definite pre-formed opinion. After seven years' labour they gave in their report. By a majority of 11 to 2 they found that vaccination was a valuable preventive of small-pox; that the process could not be safely abandoned and replaced by other precautions; and that while some alleged dangers are real they are in truth unimportant in relation to the extent of vaccination work done and are diminishing under the better precautions of the present day. More than a year elapsed before legislation was attempted and the Bill was introduced of which the third reading occupied the House of Commons to-day. That Bill contained good provisions in the way of postponing the date of compulsory vaccination of infants, providing for the treatment being carried out at home, the supplying of calf lymph, and taking advantage of Dr. Copeman's valuable discoveries regarding the special security afforded by glycerinated lymph. But the Bill made one disastrous omission. It proposed nothing in the way of revaccination. Now, experience has proved that the protection afforded by the process requires to be renewed from time to time and has amply shown that here, where it has been tried in many ways, as well as in Germany, where it has been since 1874 compulsory, repetition of the process secures an almost absolute immunity. It is in my opinion, and I am sure in that of almost the whole profession, profoundly to be regretted that the Bill contained no proposal in regard to revaccination. It is grievous to think that we lag behind and are deprived of securities which would be of such value and might so readily be obtained. But if this was a disastrous omission the Bill as it leaves the House of Commons shows another defect, for in the course of last week's debate it was decided that "no parent or other person shall be liable to any penalty under the Vaccination Act, 1867, if he satisfies two justices in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child."

The first remark that I would make is that this clause admits the status of the "conscientious objector" and gives him rights and privileges. An analysis of conscience is always attractive to a Scotsman, but I refrain from attempting to forecast how the process would work out either in regard to that of the "conscientious objector" or those of the justices of the petty sessions. But the right of a person to act according to his conscience is one which a democracy is bound to protect. Only whenever it is distinctly proved that the result of conscientious objections is really dangerous to the well-being both of the individual concerned and of the community, the community is, in my judgment, entitled to set aside the conscientious objections and to insist upon obedience. The Commissioners, who acted as a jury for the nation in this matter, are satisfied that the abandonment of vaccination would inevitably lead to formidable evils. It seems, therefore, to me that the plea of conscientious objection affords no logical ground for resistance to the law. The second remark which I would make is to inquire what the term "conscientious objector" might be made to cover. This is no easy task, but it is safe to say that it would include a great deal more than the strict use of the words should warrant. And besides if this plea be once admitted we may find conscientious objectors springing up in many other quarters. In questions of education they might make themselves heard. In regard to the payment of taxes conscientious objections, if once admitted, would no doubt spread with great rapidity; and in regard to the sanitary laws, the liquor laws, and many other subjects conscientious scruples might soon assert themselves in somewhat startling ways. But apart from speculative opinions let us see what different parties are saying about the practical result of the clause. Mr. Chaplin, who did his best to stand to his ground, says that the administration of compulsory vaccination in the future will be absolutely impracticable and no Ministry will be able to enforce it. Many share his opinion and regard the outlook as gloomy in the extreme.

The anti-vaccinationists are jubilant. One of their representatives on the Commission says that the practical conclusion of the whole matter and the results of the Royal Commission's labours amount to the abolition of compulsory vaccination for a generation. There is another class, that which believing in vaccination and desiring to see it established, yet may be ranked as advocates of "freedom before security." Some of them would not accept that motto, but I think it is just. I sympathise with the love of freedom, but would not have it override the well-being of the community. I cannot advocate freedom to do mischief and to that result this kind of freedom inevitably tends.

Digitized by Google

In this matter is it not to be feared that the House of Commons has decided contrary to its own belief? There must be but few Members who do not believe in vaccination and would not desire to see it insisted upon. Why have they voted as they did? Was it not on the part of some a weak yielding to the bigoted prejudices of their constituencies? Would they ever have dreamt of acting as they did but for this influence? And may it not be said that in the case of others the "conscientious objector" has made cowards of them all? I should be sorry to suggest that anyone sought to make party capital out of such material. May we look to the House of Lords for reconsideration of this subject? They have sometimes asserted an opinion. What is their opinion on this matter? We here at all events are, I suppose, practically unanimous in our regret that the exigencies of Parliamentary government has led us into such a retrograde position. I wish that the Legislature would boldly accept the principle that as it is mainly guided by the opinion of lawyers as to legal questions, by those of soldiers in matters military, by practical seamen and engineers in matters concerning their department, so in medical questions they would look for guidance to the medical profession and give effect to its matured opinion. Then we should have less difficulty about the question of vaccination or that of the treatment of inebriates or the prevention of the risks attending certain callings, such as those which expose the workers to lead-poisoning or to poisoning by phosphorus, and we should soon find the statute-book enriched by further beneficent enactments which would save multitudes of lives and immensely diminish sickness and suffering.

[After briefly pointing out the widespread character of the researches for the advancement of scientific knowledge now being undertaken and the necessity for the training of the medical profession and the adequate guarding of the portals thereto the President continued:—]

Medical and State Medical Organisations within the Profession.

I wish we had time to consider together the various organisations which have sprung up in the profession and have been recognised by the State or which the State has instituted for dealing with matters medical. Time would fail me to speak of the origin and the services of the ancient guilds of surgeons and the Royal Colleges, profoundly interesting as that subject would be; nor can I speak of the growth of the medical faculties of the universities, or the medical schools which are now scattered so numerously throughout the kingdom, or of the societies which do so much, not only in the great centres of medical education, but in every considerable city and in almost every district of country throughout the empire. But I must allow myself time to refer to that Association in connexion with which we are assembled here this evening. Little more than fifty years ago it took origin as the Provincial Medical Association and only after a time did it spread to London. It is forty years this week since it first ventured to cross the border and hold a meeting in Scotland. It now consists of upwards of 17,000 members, all legally qualified practitioners, admitted after careful consideration, and resident in all parts of the empire. In every district the Association is represented by branches, each of which serves important local purposes and takes its share in determining the policy of the whole Association, through its representations to and representatives on the Council. I think that the Association will do well to foster the vigour of life in the branches. Its journal has a circulation of more than 20,000 weekly and is recognised as one of the leading medical periodicals of the world. The objects of the Association are the promotion of medical and allied sciences and the maintenance of the honour and the interests of the medical profession. This is effected by the holding of meetings, the publication of a journal and transactions, the granting of money for promotion of science and for defence and promotion or maintenance of the honour or interests of the medical profession by such means and such manner as the Council may think fit, including, in particular, taking or defending legal proceedings and promoting or opposing Bills in Parliament. These objects seem to me to be worthy of the high and noble traditions of our profession. It is for the discovery and dissemination of truth and for the maintenance of the rights and influence of the profession as a whole, not for merely private ends, that the Association exists. It is our duty to inquire how far these purposes are being fulfilled. The mere numerical growth to which I have referred seems to be of itself a proof that a useful end is being served. The value of the journal to the profession cannot be overstated, especially now that such excellent epitomes of recent observation are sent out with each number. I am sure that no member can attend an annual meeting without being enriched in knowledge and inspired with new ideas. The mere contact with other minds is of inestimable value and every man who is thinking for himself or doing original work finds fresh light thrown upon his results by the results of the efforts of kindred intellects.

The Association has for many years devoted considerable sums of money to the endowment of research and much has been accomplished by its research scholars and others whom it has helped. It exerts a considerable influence in regard to public affairs connected with medicine. Our council laboriously considers all questions of medical interests which concern the profession and I can assure you that I had no idea until I came to serve on that body that its work made such demands upon the time, energy, and ability of its members, nor did I realise the far-reaching influence which it exerts. The Parliamentary Bills Committee is now presided over by a distinguished graduate of this university, who is at the same time one of the most popular Members of the House of Commons. The influence of that committee in helping to form opinion among our legislators is very considerable and I have no doubt it will increase as time advances. Apart from that committee the Association is able to intervene with good effect in other ways. No better illustration could be offered than our recent experiences in relation to the Medical Department of the Army. For the Association had its share in making the representations to the Minister of War which have resulted in so hopeful a reorganisation of the whole Army Medical Service. I can speak personally of the courtesy and encouragement with which your deputation was received and I am sure that no one who heard the statement by the Marquis of Lansdowne at the great banquet given by the Lord Mayor of London could fail to see that the intervention of the Association had been attended by the happiest result. Not that we are to claim all the credit, for the hard facts of the state of the Service had been pressing themselves upon the attention of the authorities and many influential representations had been made regarding the questions involved. As time goes on and our influence increases the Association may often be able to perform like service for the profession and for the country.

The General Medical Council.

Among the institutions which, although suggested by medical men, were instituted by the legislature I should mention first the General Medical Council. We have now had forty years' experience of that body and I for one think that it has done good service to the profession and the State It has raised the standard of preliminary examinations; it has extended the period of medical study; it has set its face against the custom of legally qualified practitioners evading the law by what is known as covering others who are not qualified; and it has recently passed a strong resolution against the employment of unqualified assistants, which, however hardly it may press upon the individuals who are worthy of all sympathy, is undoubtedly sound in principle. Its powers have been more limited than might have been desired and perhaps they might be extended and increased with advantage. To take a single instance, I would suggest that just as a diploma of a university or a college entitles the holder, whoever he may be, to be placed upon the Medical Register and gives him all the privileges attached to such registration, so the decision of the General Medical Council that any person on the Register is no longer worthy to have his name retained upon it should *ipso facto* deprive him of the diploma or the degree upon which he had been registered. It seems absurd that there should be a necessity for renewing and repeating the trial in such a case. The decision of the supreme court of the profession should, I think, be held to cover and to include that of the licensing bodies and even of the universities. The legislature is already acquiring the habit of now and then referring a question or an opinion to the General Medical Council, and it seems to me that much would be gained if this expedient were more frequently adopted in regard, not to that Council alone, but to the Association which we here represent.

The Public Health Executive.

This brings me to speak of the Public Health Executive, the officials who are entrusted with carrying out the laws relating to disease and its prevention. The formation of the department was—like most British institutions—an evolution rather than a creation. For when the Government felt the need of establishing such a branch of the executive it did not construct a new board or appoint new officers beyond what was absolutely necessary, but rather laid additional duties upon boards and officials already existing. There is no need for me to explain the precise arrangements adopted either in England or in Scotland, but in a general way I may say that in the former the new duties were entrusted to what had previously been the Medical Department of the Privy Council, the engineers of the Local Government Office, and the members of the Poor-law Board; while in the latter the board originally established for carrying out the Poor-law of 1845 was turned to account for the new purpose. They were named in each division of the country "The Local Government Board." But these boards were not entrusted with the carrying out of the whole work relating to public health. Sir Benjamin Ward Richardson pointed out nearly twenty years ago that that work is too widely distributed. He said that so much had to be done by the President of the Local Government Board, so much by the Secretary of State for the Home Department, so much by the Registrar-General, so much by the Chief Commissioner of Works, so much by the Lord President of the Privy Council, and so much by the President of the Board of Trade, and all that without reckoning the heads of the army and navy departments, the Postmaster-General, and even some other important officials. On the other hand, the duties of the Local Government Board naturally included, considering its mode of construction, much that might well have been relegated to other departments—as, for example, many matters relating to Poor-law administration. All this might surely be simplified with much advantage. The department has grown so great and so complicated and the importance of the work of some of its parts has become so much more appreciated that it demands reconstruction. I should like to see the Local Government Board entrusted with every question which bears upon the prevention of disease. It should have two divisions—one dealing with the questions of local administration and the other with the public health. These two sub-divisions would cover the whole work at present undertaken and which properly belongs to this great department. The President of the Board thus reconstructed should be recognised as an official of the higher rank and should indeed be not only a Minister, but a Secretary of State for the department. It would be a great benefit that he should be an officer of such dignity and influence as that he would be able to secure in the Cabinet and in Parliament due attention to the subjects with which he has to deal. He might be a Member of either House, but considering the frequency with which financial questions must emerge it would probably be better that he should sit in the House of Commons. He would, of course, have a Parliamentary and a permanent Under-Secretary, the former of whom should also, as at present, be a Member of the House, who should take his share in the administration of the department, and in the absence of his chief answer questions and be available for reference and inquiry in the House on any subject connected with the department. The sub-department should also be maintained, at which information, advice, and direction upon all sanitary questions may be obtained, while at the same time it continued to organise and carry out scientific investigations somewhat on the lines which are at present followed. There should also be other sub-departments dealing with various branches of the subject, as, for example, with the registration of births, deaths, and marriages; with the incidence of notifiable diseases, epizootics, and diseases of plants (unless this is sufficiently provided for by the Board of Agriculture), with meteorological and other reports; with the working out of the various Public Health Acts; with the Vaccination Acts; the medical questions arising under the Factory Acts; with the care of the insane; with all questions as to the disposal of the dead, and such like. There are already officials entrusted with nearly all these duties and in many respects the department is admirably equipped. All that would be required in many instances would be the grouping of them afresh and the clearing up of the precise details as to their work.

I am well aware that it is a serious thing to suggest the addition of even one Minister to the Cabinet and still more to suggest that he should take so high a place as that of Secretary of State; but even with the difficulties which I admit it seems to me obvious that the great importance of the public health, equalling, indeed, that of almost any other department in the State, warrants such a step. And as I believe that history will regard it as one of the chief glories of the reign of Her Majesty that the nation thus awoke to the importance of the question of public health, so I should desire that the executive which subserves it should in that reign also be put upon a footing worthy of the greatness of its work. In respect of the duties of administration as well as of legislation such changes as I advocate would give a great increase of efficiency.

Conclusion.

But I have reached the utmost limit of my time and must hasten to conclude. I have briefly reviewed what I consider the chief relative duties incumbent upon us and the community. I have shown that in our personal relationships things stand fairly well, but that in regard to preventive medicine the attitude of the community and the State leaves much to be desired. I have shown also reason to think that there is room for more generous dealing in respect of the endowment of research and of universities and schools. But I should sum up by saying that our part is to perform our duty conscientiously and to the best of our ability. It is not by banding ourselves like a trades union and crying aloud about our wrongs, real or imaginary, but by the efficient discharge of our own duty that we shall best aid the community to perform theirs. When each of us does his best for every patient and for the State, not with eye-service or as men-pleasers, but with a profound appreciation of our grave and sometimes awful responsibilities, then shall we win the place in public esteem which will bring to our beloved science and art and to us the recognition to which they and we are entitled.

SECOND GENERAL MEETING.

The second general meeting was held in the M'Ewan Hall on Wednesday afternoon, the PRESIDENT being in the chair.

The recommendation of the Council that the invitation to hold the next annual meeting at Portsmouth be accepted, and that Dr. Ward Cousins be the President-elect, was unanimously agreed to, and Dr. WARD COUSINS expressed his thanks for the honour conferred upon the Portsmouth Branch and upon himself.

The PRESIDENT then introduced Professor FRASER, who delivered the Address in Medicine, which will be found on page 243.

At the conclusion of the address a vote of thanks to Professor Fraser was proposed by Sir WILLIAM BROADBENT and seconded by Professor OSLER.

After this the hall, which had been very full, rapidly emptied and, finally, there remained only some 25 members in the body of the hall and about 10 members of the Council on the platform. Sir Thomas Grainger Stewart left the chair, which was taken by Dr. Saundby.

Dr. BRASSEY BRIERLEY, who had given notice of moving certain alterations in the by-laws, withdrew them. He then moved the following as an additional by-law:—

A Parliamentary Committee shall be elected annually, and shall consist of one representative nominated by each Branch having over 150 members, four members elected by the Council of the Association at its first sitting, and three members elected by and present at the annual meeting, but none of these latter shall be already a member of the Central Council.

The Parliamentary Committee shall meet at least six times a year, and a sum not exceeding £2,000 a year shall be placed at its disposal.

Mr. BOUSFIELD seconded.

Dr. SAUNDBY pointed out that this would practically disfranchise all the branches, 17 in number, who had under 150 members.

Mr. R. B. ANDERSON having made a few remarks which called forth a spirited and dignified protest from Dr. Saundby, Dr. Brassey Brierley, in the interests of peace, withdrew his motion.

Dr. J. MYRTLE had given notice of the following—

That whereas long delay has taken place in giving effect to and carrying out certain resolutions passed at general meetings of the Association, this meeting calls upon the Council to at once take the necessary steps to apply to the High Court to legalise the new Articles and Memorandum of Association, and, upon this being granted, to forthwith undertake the medical defence of members of the Association.

He now wished to leave out everything after the word

Digitized by Google

"Memorandum of Association," but Dr. Saundby would not allow this because it would open a door for too wide discussion.

Dr. HADDON moved, "That the scientific grants be discontinued," but could find no seconder.

The meeting then terminated.

THE SECTIONS.

The Sectional work commenced on Wednesday, July 27th, in all the Sections.

MEDICINE.

WEDNESDAY, JULY 27TH.

Dr. G. W. BALFOUR, consulting physician to the Edinburgh Royal Infirmary, delivered the following Presidential Address to the Section, entitled

Personal Experience of an almost forgotten Episode in Medical History.

It has struck me that a few words from personal experience in regard to a now almost forgotten episode of medical history might prove both interesting and instructive. There are not many now alive who remember the time when blood-letting was the panacea for almost every ailment, and when patients could be no longer safely bled they were certainly leeched or cupped. There must be few survivors of the time when one of the earliest lessons in surgery was to distinguish between an ordinary blood-clot and one which was buffed and cupped, or who were taught that in uncomplicated pneumonia such confidence was to be placed in blood-letting that "the only essential action of the prognosis was the day of the disease on which the treatment was commenced," as it sometimes failed when delayed more than two or three days from the commencement of the disease. Yet such were the earliest lessons in medicine which I received, lessons which were daily exemplified in the wards of the old Royal Infirmary. When within a year of my graduation I made my way to Vienna with the view of studying homœopathy, which had just made a convert of one of our ablest professors (Henderson), I occupied my time at first in improving my knowledge of percussion and auscultation under the world-renowned Dr. Joseph Skoda, and you may imagine my astonishment when I found that in his wards the severest cases of pneumonia were treated with poultices and regulated doses of extractum graminis (hay tea) and with nothing else unless much pain was complained of, when a few grains of Dover's powder were superadded. The excellent results obtained by Skoda with his hay tea sufficed to dispel the clouds of mysticism which had been raised by homœopathy, while the success of Dietl in the same class of cases in another hospital with simple aqua colorata showed that there was nothing specific even in hay tea and confirmed the unmistakeable conclusion that, as Skoda put it, pneumonia tended not to dissolution but to resolution and that the large blood-lettings thought necessary for its treatment were, to say the least, uncalled for. Much stress continued to be laid upon the necessity for blood-letting in the Edinburgh school, though it had ceased to be carried to such an extreme as in the immediately preceding generation. On my return from Vienna I read to the Medico-Chirurgical Society of this city a report of what I had observed in the wards of Skoda, with an account of 392 cases of pneumonia treated on what might be termed the expectant principle and showing a mortality of only 54, or 1 in 7¼, equal to 13·7 per cent. I pointed out that the Vienna cases were certainly not less sthenic than those in Edinburgh, that they had the disadvantage of being daily unceremoniously auscultated, percussed, and lectured over, which was not the custom in our infirmary in those days, and that they had not the advantage of having been freely bled, yet their mortality was only 13·7 per cent. In the reports of our own infirmary during the five years and three months from July 1st, 1839, to Sept. 30th, 1844, there are recorded 253 cases of pneumonia which escaped the lecturing and had the advantage of having been freely bled, and of these 91 died, a mortality of 1 in 2·78, or 35·9 per cent., showing a proportion of recoveries of nearly 3 to 1, or over 20 per cent. in favour of those who were not bled, to say nothing of the time gained by their more rapid recovery or of the less exhausted condition in which the patients were left whereby they were sooner fit to return to the duties of active life. I urged upon the society the importance of giving the eclectic system of treating pneumonia a fair trial, throwing out the suggestion—made to me by a distinguished Austrian physician—that possibly some change in the type of the disease might underlie the apparent change in its relation to perturbative treatment. My words fell on deaf ears and the conclusion arrived at may very well be summed up in the words of one of the ablest physicians of the day—Dr. John Gairdner: "Nothing was better established than the good effect of blood-letting in Edinburgh, whatever might be the case in Vienna. ..... Of the benefits of early blood-letting he entertained no doubt whatever; they were positive, immediate, unequivocal, and admitted by almost every physician whose experience and judgment entitle him to consideration; and if Dr. Balfour or anyone else could shake his conviction in the truth of his opinion he would also succeed in producing in his mind a general distrust of medical evidence in all cases of every description, since in no case whatever can we have evidence which is stronger or more satisfactory." I need not pursue the subject further; the eclectic treatment passed gradually into the hands of the general practitioner, and within less than ten years the late Professor Bennett wrote: "It is admitted that the practice of bleeding in acute inflammations has within a recent period undergone a great change; that whereas it was formerly the rule to bleed early, largely, and often repeatedly, now such bleeding is rarely practised and is not necessary." After this we had the war of opinions in regard to whether this change was due to a better knowledge of the natural history of the disease and of its pathology or to an actual change in the type of disease which had become less sthenic in character and no longer required the same heroic remedies. But into this I need not enter; it forms part of the history of medicine, and the object of this short sketch is to point out the importance of a knowledge of this subject. We are now on the threshold of new discoveries and of quite a new pathology, which is indeed but a higher development of ideas which have long been slumbering in the professional mind—the connecting links being Dwight, Raspail, Hallier, and Pasteur—but which seem likely now to attain a development of the highest importance for the well-being of mankind. It is well, however, in the light of the past to remember that disease may be recovered from under many different forms of treatment. The practical certainties of our art in all ages have been sufficient for the welfare of mankind and we must be careful never to subordinate to any vague ideas of what may possibly be curative of disease that which is, after all, the paramount object of our art—the relief of suffering.

A discussion was then opened by Dr. ALEXANDER JAMES on

The Clinical Varieties of Hepatic Cirrhosis.

Dr. JAMES began by pointing out that as regards causation, symptoms, and course the phenomena of hepatic cirrhosis at first sight appeared more clear, well defined, and comprehensible than almost any other disease. In atrophic cirrhosis, for example, we have an irritant, usually alcohol, carried to the liver. There it sets up irritation, as the result of which cell proliferation occurs round about the interlobular branches of the portal veins. Those cells, becoming fibrous tissue, contract, compressing and destroying the hepatic parenchyma, and compressing and obstructing the portal veins. Hence arises congestion of the mucous membrane of stomach and intestine, dyspepsia, hematemesis, ascites, enlarged spleen, &c. In the so-called biliary cirrhosis, there occurs a cell infiltration among the cells of the liver lobules, the result mainly of some biliary irritation. Hence arises the jaundice, and in this variety we have a large smooth liver but no portal obstruction, ascites, hematemesis, or enlarged spleen. But there was, he thought, no doubt that an extended observation of cases showed that liver cirrhosis was not always such a well-defined disease. Cases occurred which began with jaundice and an enlarged liver and in which in time the jaundice disappeared; and with the disappearance of the jaundice symptoms of portal obstruction showed themselves—ascites, enlarged spleen, &c. The author believed that the disease—acute yellow atrophy—showed many resemblances to cirrhosis, for in the less rapid forms of it there were found not only symptoms such as one meets with in cirrhosis (gastro-intestinal irritations, hæmorrhages, &c.), but on post-mortem examination there is found, combined with the destruction of liver cells, an increased production of fibrous tissue. The author next discussed how an irritant could at one and

Digitized by Google

the same time produce destruction of liver cells and increase of its connective tissue, after which he pointed out that in liver cirrhosis, although the irritating factors might be many, the results were the same. He then delineated four types of hepatic cirrhosis which he thought might be regarded as legitimate varieties—(1) the purely atrophic, (2) the purely hypertrophic, (3) the transitional form, and (4) the form which, occurring in younger individuals, might be the result of congenital causes or of some local condition, such as peritonitic adhesions.

In the discussion which followed Dr. ROSENSTEIN (Leyden) thought that alcohol as a factor in the production of cirrhosis of the liver was very much overrated. In Holland, where enormous quantities of alcohol were drunk, cirrhosis was not met with in like proportion.—Dr. OSLER (Baltimore) thought that the possibly bacterial origin of some kinds of cirrhosis was worth bearing in mind.—Dr. BRADBURY (Cambridge), Dr. EWART (London), Dr. BOYD (Belfast), Dr. HANDFORD (Nottingham), Dr. GERHARDT (Berlin), Dr. DRUMMOND (Newcastle), Dr. ROSENBACH (Berlin), and Dr. ALLISON (Newcastle), also took part in the discussion, the general opinion being that although many anatomical types existed with well-defined pathological differences, it was not always easy to trace the clinical distinctions, excepting only that the small atrophic liver was usually associated with ascites and jaundice was a subordinate feature; while, on the other hand, the large hobnailed liver was frequently associated with jaundice and the ascites was less marked than in the other kind.

A paper on

The Bacteriology of Cirrhosis of the Liver.

(illustrated by numerous lantern slides) by Professor J. G. ADAMI (Montreal), was read by Professor WM. OSLER (Baltimore). It was at the outset pointed out that the experimental injection of alcohol results in fatty liver with at most only a very slight amount of fibroid change in the portal areas. Not a single observer has by this means, and after treating animals for many months, been able to produce anything at all resembling the extreme deposit of fibrous tissue met with in typical hobnailed liver. On the other hand, evidence has been accumulating—notably in India—that extreme cirrhosis may attack children and adults who have never taken a particle of alcohol. Within the last few years some French pathologists, notably Hanot, have regarded the enlarged cirrhotic liver which is associated with jaundice as being of infectious origin and have made use of the term, *le foie infectieux*. But no microbe has been identified and the only case in which a diplococcus was isolated was complicated by endocarditis and suppurative meningitis. After alluding to the possible association between cases of "Hanot's cirrhosis" and "epidemic jaundice" the author passed to the description of his own researches made in connexion with a very remarkable disease affecting cattle in a limited area in Nova Scotia—the so-called Pictou cattle disease—of which the main lesion is a singularly extensive cirrhosis of the liver. This disease appears to have been endemic for forty years in this district, slowly spreading from one animal to another. "The first symptom noticed is a bitterness in the milk and in time the beast dies slowly from exhaustion." The author killed and examined some thirty animals, the main lesions being an extreme condition of generalised hepatic cirrhosis, not only periportal but pericellular, the organ being enlarged and smooth; the gall-bladder was full and fæces were stained and a moderate amount of ascitis was present. Numerous follicular ulcers were present in the fourth or true stomach. These gave the impression that the earliest lesions are the gastric changes, which are followed by the infection of the abdominal lymphatic system and portal area. The spleen was not markedly enlarged. From all the animals a characteristic micro-organism was obtained. It was a polymorphic organism, its most usual form being a short bacillus with polar staining, resembling in some respects the micro-organism of hæmorrhagic septicæmia in the lower animals, but differing in essential features. It was pathogenic for rabbits, guinea-pigs, and mice. The author was struck with the clinical similarity between this disease and portal cirrhosis in man, and he has since endeavoured to reveal a microbe in cases of the latter. In one case a microbe was procured, but it died on the fifth day. The chief difficulty lay in the staining of the micro-organism in the tissues, all colours tried having faded so rapidly. This was overcome by bleaching very deeply stained sections in the sunlight for a short time daily for two weeks or more. In this way, using carbolised fuchsin, the author had been able to discover the same characteristic organism in the cells of all the cirrhotic livers he had examined during the last three years—26 in number—whether of the small shrunken type or the large hobnailed type, whether associated with jaundice and without ascites or associated with ascites and without jaundice. Lantern slides of the micro-organism were exhibited on the screen and the author entered very fully into the methods of staining and of revealing it in the liver cells. It is extraordinarily minute, requiring some experience on the part of the observer and the highest powers of the microscope ($\frac{1}{75}$ or $\frac{1}{90}$ in.) to discover it in the liver cells, in which, however, it is to be found in great abundance. According to the depth of the stain so does it appear, either as an ovoid bacillus (which might easily be mistaken for some stained deposit in the liver cells) or as a minute diplococcus surrounded by a distinct halo. The author knows of no organism so minute, save that recently described by Nocard and Roux as being the causative agent of the contagious pleuro-pneumonia in cattle, and the strain upon the eye of the observer is very severe. The question as to whether the micro-organisms in the human and bovine livers are identical is impossible to decide absolutely at present. It must suffice for the present to state that a characteristic microbe is present in the Pictou cattle disease—a disease having certain close resemblances to progressive cirrhosis of the liver in man—and that large numbers of a micro-organism have been revealed by special methods devised by the author in the lower cells in cases of cirrhosis in the human being; and, finally, that these two micro-organisms greatly resemble each other under the microscope. In an appendix to the paper the author mentioned a case of cirrhosis on which he had just made a post-mortem examination, and in which he had discovered the same micro-organism. Time had not permitted him to make cultures, but this he was about to do. The micro-organism isolated from cattle is polymorphic, appearing as a small diplococcus when grown on broth and tending to assume a distinctly bacillary form when grown on solid media.

Dr. WILLIAM BAIN (Harrogate) read a paper on:—

The Extent of Congestion of the Liver not Dependent on Organic Disease.

The type of disease considered was a chronic form of active congestion independent of organic disease, apyretic, and having existed for a few weeks or months. After considering some of the signs and symptoms of the condition he passed to consider the treatment, of which there are two kinds—that which can be carried out at home and that which necessitates going to a spa. The former might consist of a daily bath (70° to 90°), and some counter-irritation to the liver on alternate nights with cholagogues. The spa advocated was the sulphur spring at Harrogate and in some cases the Kissingen waters, either of which might be combined with deep massage of the liver.

Professor MCCALL ANDERSON (Glasgow) read a paper entitled—

A Plea for the more General Use of Tuberculin.

At the outset he expressed his regret that the wide-spread laudation with which the tuberculin treatment was ushered in had given place to an almost total neglect of it by the bulk of the profession in this country. The reasons of this were not far to seek. Too much was at first expected from it and it was used in too wholesale a manner; the cases were not selected carefully enough and the doses were generally too great or the intervals between the injections too short. After giving the original tuberculin a fair trial he was satisfied of its value and gave cases illustrative of its use (*a*) for diagnostic purposes; (*b*) for discovering foci of disease in unexpected situations; and (*c*) as a curative agent. He had not had sufficient experience of the new tuberculin to enable him to compare it with the old, but he was rather inclined to think that the former is the milder and safer of the two for purposes of treatment, while the latter is probably more useful for purposes of diagnosis. The latter is certainly much cheaper, the full dose costing less than a penny, as against seventeen shillings in the case of the new tuberculin. While admitting the accuracy of many observers to the effect that the treatment is often only temporarily beneficial, he suspected that this not infrequently arises from omitting to act on the principle that there are two almost equally potent factors in the production of tuberculous disease—viz., (*a*) the tubercle

Digitized by Google

bacillus, and (*b*) the soil favourable to its growth and development. In all cases, therefore, the tuberculin injections must be combined with good food, pure air, cod liver oil and other anti-strumous remedies, if permanent beneficial results are to be obtained.

Professor ROSENBACH (Berlin) read a paper on Locomotor Ataxy; and

Dr. T. F. S. CAVERHILL read a paper on the Open Air Treatment of Consumption, and exhibited six patients who had been under treatment at Nordach. The discussion of this subject was adjourned to the next meeting.

SURGERY.

WEDNESDAY, JULY 27TH.

The Presidential Address in this Section was delivered by Dr. JOHN DUNCAN, consulting surgeon to the Edinburgh Royal Infirmary, who chose as his subject

Modern Operating Theatres.

After a few words of welcome to his hearers Dr. Duncan said: To one who can look back over thirty or forty years no fact in medical education bulks more largely than the increasing importance of our examination system. Formerly examinations were meant to eliminate the useless; now they dominate the teaching. In some respects this is matter for regret, but there is hope that if a little breathing space be accorded we shall gradually educate the examiners to recognise that the candidate is not a finished practitioner familiar with every meaningless detail, but that the chief business of the teacher is to make men think and of the examiner to find out how far that has been successful. Meantime, however, this educational movement has done much good and one of the most distinct benefits has been increased attention to the practical and clinical. You will find evidence of this in the laboratories and museums which are now attached to every department in our new university buildings and in the associated schools and which culminate in the admirable laboratory of the Royal College of Physicians of Edinburgh and in the important Museum of the Royal College of Surgeons of Edinburgh. The managers of our infirmary have not been slow in responding to this movement. Extensive additions have been made to the pathological and other departments, but I may specially direct your attention to two points which are surgically interesting. The first is that we have now all but completed the arrangements whereby a surgical theatre shall be placed at the disposal of each set of wards. When not many years ago we moved into the present buildings we found that one spacious theatre had been provided in which it was intended that all operations should be performed. But the antiseptic system has thrown open to surgery so wide a field and the population of our towns has so greatly increased that our youngest surgeon now performs almost as many operations as were performed in the whole infirmary in the days of Syme. Moreover, students do not flock nowadays to the surgical theatre as the populace used to flock to an execution, or at least not to the same extent as formerly. The glorification of mere manual dexterity has also greatly diminished. It is seen that if you know what to do there is little difficulty in doing it. And so a surgical operation has come to be regarded as an incident in a case, and the theatre has become an appanage to the ward, in which whatever manipulation is necessary may be carried out in the way most advantageous to the patient and most beneficial to the student as a sequel to the diagnosis and a preliminary to the after-treatment. You will see also that not only have the new theatres been constructed according to modern ideas, but that the older have also been remodelled on the same lines. Our managers deserve all credit for this endeavour to meet modern requirements, but I am not of those who have great faith in surgical upholstery. I cannot believe that the expense which has been incurred here and elsewhere in transforming cleanly and well-ventilated theatres into stuctures of tiles and glass was a necessary expenditure. It may be said that it is all in the right direction, but there are considerations worth bearing in mind before the money of a charity is expended in costly reconstruction. In the first place smooth and impermeable materials are not necessarily those which are most easily rendered aseptic. It is a fallacy to suppose that you render a theatre aseptic by douching its floor with antiseptic solutions I am not sure but that the cleansing of a good old wooden floor is antiseptically as satisfactory as the treatment applied to its modern substitute. In the second place, if the principle be sound on which this change has been made, much more is necessary to carry it to a logical conclusion. The emanations from spectators are more dangerous than those from walls and floor. Must we not, therefore, follow those who have cut the spectators off more or less by an impermeable but transparent screen? The emanations from the operator and his assistants are far more likely to reach the wound than those from spectators. So I picture to myself a time when everyone concerned in an operation—patient, surgeon, and assistants—having been rendered from top to toe cutaneously aseptic, shall cover each natural orifice of the body with an antiseptic mask, and clothing themselves in raiment scientifically pure shall pass into an atmosphere freed from germs by the air pump and by heat. Many years ago we had here a little controversy as to the value of the spray which was then in vogue. Incidentally I convinced myself by experiment and clinical observation that in surgical operations the air was a negligible quantity. If that be so—and if not absolutely true it is very near it—it would be unfortunate that in cases of antiseptic failure the surgeon should be led to seek in unfavourable surroundings for a loophole of escape from self-blame, or to believe that he cannot operate with perfect success save in a glass case or a crystal palace. Our ingenuity need not be directed to the air, which may be trusted to efficient ventilation and the germicide action of the tissues. The skin, the instruments, the apparatus, are the true objects of our care. The other improvement to which I venture to direct your attention is the introduction of electricity into the infirmary. For 30 years I have preached in and out of season the surgical uses of electrolysis, but I feel assured that even now it has not met with the appreciation it deserves. Yet in cirsoid aneurysm no other treatment can be compared with it for a moment. In nævus of the usual mixed variety if you desire to avoid a scar there is nothing so sure and so safe. It does excellently in some other forms of angioma. It gives good results in goitre. It is useful in uterine fibroma. It is an efficient depilatory. Many of these are common diseases which ought to be treated by the ordinary surgeon, and I have hope, now that electricity is being introduced into our infirmaries, that electrolysis will come into greater favour and that the surgeon will have no more hesitation in employing it in suitable cases than in performing lithotomy or amputating a finger.

A discussion was then opened by Mr. BENNETT, Professor of Surgery in Trinity College, Dublin, upon

Injuries of the Elbow-Joint.

He commenced by saying that the subject was exceedingly vast, and therefore he would not attempt to do more than speak on a small portion of it. Our museums and the clinical experience of all surgeons show that errors of diagnosis are frequently made in connexion with fractures of the lower end of the humerus and with displacement backwards of the radius and ulna. There are four reasons for much obscurity in connexion with these injuries. In the first place, the text-books are by no means agreed as to the terms which should be applied to the several parts of the lower end of the humerus; the internal condyle is sometimes spoken of as the internal epicondyle, and sometimes as the epitrochlea, and occasionally the trochlea and its epicondyle are put together and called the internal condyle. A similar confusion exists with respect to the parts on the outer side—namely, the capitellum and the external condyle. With such confusion in the terms employed it was easy to understand that the same name might be employed by two surgeons for two injuries essentially different. Another reason for errors in diagnosis is the very rapid swelling which comes on in these cases, and a surgeon who sees a case only some weeks after an injury may have no difficulty in recognising a mistake in diagnosis made by a surgeon who saw the case a few hours after the accident. A consideration of the difficulties caused by swelling should teach us the doctrine of charity when dealing with the mistakes made by others. A third point in the consideration of these cases is the absence of reference in the standard text-books to incomplete dislocation of both bones backwards. To judge by museum specimens the incomplete variety was even more frequent than the complete form, though of course it is possible that this may be in part due to the easier recognition, and therefore reduction, of most of the complete cases. A fourth cause of confusion is the incompleteness of our knowledge of

Digitized by Google

the pathological anatomy of the lesions of the lower end of the humerus. In 1869 Professor Smith put to him the question, "Why in compound separation of the lower end of the humerus does not the elbow joint suppurate?" This was in the days before antisepsis. Hutchinson had advised excision of the protruding end of the diaphysis; but observation had shown that as a rule suppuration did not occur in the joint, and experiment had indicated the reason thus: when the lower epiphysis is broken off it carries with it the epiphysial cartilage and also the periosteum of the lower portion of the diaphysis, which is stripped off the bone. In this way the periosteum protects the synovial membrane and the joint is not involved at all, though the end of the diaphysis is often thrust through the skin.

This paper by Professor Bennett was illustrated by a large number of very interesting specimens, both moist and dry, of fractures of the lower end of the humerus and of backward displacement of the radius and ulna.

Dr. ROBERTS (Philadelphia) expressed the opinion that ankylosis of the elbow-joint was always due to incorrect coaptation of the fractured surfaces, and though it was possible that some of the loss of movement might be due to excessive formation of new bone, yet it was by no means a common cause and the other reasons generally given for limitation of movement, such as thickening of the capsule, had practically nothing to do with it. Another proposition he would like to lay down was that it was desirable to preserve the normal angle between the humerus and ulva. The "gun-stock" deformity is probably always due to fracture of the internal condyle. Mere alteration of the angle in itself will not impair the utility of the joint, for this angle varies in healthy subjects, but it has an unpleasant appearance. To get good results it is necessary to fix the fragments firmly, and Dr. Roberts thought that the use of long nails in cases of difficulty was a useful method. They might be driven right through the skin, and then be withdrawn in two or three weeks. He had devised some special steel nails and other instruments for the purpose. In obscure or severe cases an exploratory incision might be required and that was best made in the groove between the biceps and the supinator longus. The best position in which to put up a fracture was the not quite fully extended one, though many used a position of extreme flexion.

Professor CHIENE (Edinburgh) remarked that injuries in the neighbourhood of the elbow-joint could be treated in three positions. 1. The fully extended position was best for severe cases in which it was necessary to keep the patient in bed; if necessary, strapping and a weight and pulley might be used as in the lower limb. 2. The rectangular position was suitable for cases of fracture of the olecranon *without displacement*. 3. In all other fractures the fully flexed position is best; no anterior pad should be used beyond a little lint, and the limb should be fixed to the chest with a layer of lint between. After a week massage might be employed and a little later movements may be attempted.

Mr. BRYANT (London) accepted Professor BENNETT'S explanation of what took place in a separation of the lower epiphysis of the humerus, and as a confirmation of it he mentioned the great thickening of the lower part of the diaphysis in these cases resulting from the deposition of bone between the raised periosteum and the diaphysis. He further remarked that the extended position was by far the best in which to examine injuries about the elbow, as every point of bone could be felt. The extended position, moreover, was frequently the best position in which to put up the limb, at all events at first.

Mr. DALZIEL (Glasgow) mentioned that during the last few years he had seen six cases of stiff elbow, in each of which a fall on the hand had occurred causing a splitting off of the capitellum, which often is rotated so that the articular surface is applied to the lower end of the humerus. Ankylosis may result, or non-union, or the inner fragment will continue to grow while the outer fragment does not grow; and in this way much deformity may result. It is important to bear in mind that this fracture is not a separation of the epiphysis, but a true fracture. It never occurs after puberty. Nailing the separated fragment is the best treatment and has proved successful even seven years after the accident.

Mr. KEETLEY (London) thought that the absence of suppuration in the elbow-joint in the cases of compound separation of the lower epiphysis of the humerus was probably to be explained by the joint having been rapidly shut off by adhesions. He agreed with Dr. Roberts that displaced bone was the chief cause of ankylosis, but he did not approve of using nails; an incision was not rarely required, and then sutures could be employed. He was of opinion that "passive exercise" of injured joints was much overdone.

Mr. JORDAN LLOYD (Birmingham) considered that pure dislocations of the elbow are extremely rare, though fractures in the lower end of the humerus are often mistaken for them. Splitting off of the capitellum is not rarely a result of a fall on the elbow, the olecranon from its shape acting as a wedge. The injury is probably common in children and is often overlooked; it may heal well and cause no loss of mobility of the joint. The most common cause of stiffness of the elbow is excess of passive movement; the joint after a fracture should be kept at rest for from four to six weeks. A crushing up of the olecranon leading to narrowing of the great sigmoid notch might occur from a fall on the elbow and might lead to great difficulty in the reduction of the dislocation which was generally present.

Mr. J. HUTCHINSON, jun. (London), attributed much of the difficulty of diagnosis in cases of injury to the elbow to the fact that frequently the injury is complex, and he presented a skiagraph which showed multiple lesions in the neighbourhood of the joint. He could not agree with Professor Annandale's opinion, as shown by the numerous specimens in the Pathological Museum, that in compound fracture into the joint excision should be done. He thought that we should remove as little as possible in such cases.

Professor BENNETT, in reply, mentioned that he had brought some skiagraphs which demonstrated very clearly the deposit of subperiosteal bone in cases of separation of the lower epiphysis of the humerus to which Mr. Bryant had alluded.

The PRESIDENT summed up the discussion, saying that there were two great difficulties in these fractures about the elbow; firstly it was difficult to put the fragments in position, and secondly, it was difficult to maintain the mobility of the joint. He thought that passive movements should be applied with great care; in the morning the joint might be flexed and in the evening it might be extended. This was all that was needed.

Intestinal Obstruction.

Professor KOCHER (Bern) read a paper on Intestinal Obstruction. It is still only too common, he remarked, to find cases treated by drugs before the surgeon is consulted. He had had 77 cases of intestinal obstruction (excluding cases of disease of the rectum and external hernia); of these, 26 were due to malignant disease of the bowel, and he resected the intestine in 24 of these cases with only 4 deaths. In 19 cases tuberculous masses had produced stricture of the bowel; in 18 of these he operated and only 1 patient died. If the moribund cases and those where no operation was done were excluded there remained 38 cases in which an operation was performed, and in these the mortality was only 18 per cent. It was, however, curious that in the slighter cases, where the ileus might be said to be symptomatic, the mortality was much higher; of 7 cases of volvulus there were 5 deaths. In fact, in the simpler cases the death-rate was 59 per cent. The logical deduction from these statistics is that the great mortality is not due to the operation. The cause of death in most cases was septic absorption from ulcers occurring in the bowel above the obstruction; these ulcers were usually attributed to pressure from fæces, but they occurred even when the fæces were liquid; they were really due to over-distension, which led to impairment of the epithelium. It was necessary to relieve the distension as soon as possible, and this might be done by a small incision, a radical cure being postponed to a later date. Finally he urged that surgeons should be called in to see a case of obstruction before any drug is given, and it was very advisable for the surgeon to have the benefit of a physician's opinion when making the diagnosis.

Œsophagotomy.

Mr. W. THELWALL THOMAS (Liverpool) read a paper on three cases of Œsophagotomy for Swallowed Toothplates. In the first case repeated attempts had been made to dislodge the plate, and though it was easily removed by operation the patient sank and died; in the two other cases, where no forcible attempts to remove the plates with forceps had been made, recovery was rapid, uneventful and complete. Mr. Thomas thought that a metal-ended bougie would be better than the usual gum-elastic probang as being more likely to give an audible "click" when touching the toothplate and

Digitized by Google

that the cases showed the undesirability of any prolonged attempts at extraction through the mouth.

Hepatectomy.

Mr. MAYO ROBSON (Leeds) read a paper on three cases of Partial Hepatectomy for Cancer. He remarked that out of nearly 300 operations on the liver and bile-tracts, of which number 35 were cases of malignant disease, there were only 3 cases in which he had thought it feasible to attempt removal of a small portion of the liver with the affected gall-bladder and duct. Of these 3, 1 died in a few hours, but the other 2 completely recovered from the operation but died some months later from recurrence. In all the 3 cases he had applied an elastic ligature beyond the growth, keeping it from slipping by knitting needles. The mass having been brought out of the abdomen was cut off. Mr. Mayo Robson remarked that in two cases in which he had closed the abdomen, thinking malignant disease was present, complete and permanent recovery had followed. There were probably cases of inflammatory thickening which disappeared after removal of the cause, and he thought that in doubtful cases an exploratory incision was advisable. In conclusion, he enunciated the following propositions:—1. Seeing that statistics agree in showing the frequent association of gallstones and primary cancer of the gall-bladder and liver, it is desirable that cases of cholelithiasis should be treated surgically at an earlier stage than has hitherto been the custom. 2. In all cases of tumour of the gall-bladder, even if unaccompanied by symptoms, an operation is advisable, and the obstruction, usually a calculus, should be removed. 3. If these rules were followed, probably primary cancer of the gall-bladder and liver would be rarer. 4. If early operation in cases of tumour of the gall-bladder were followed out, then, even if primary cancer had commenced, it would be in an early stage, and a complete recovery by partial hepatectomy might be hoped for. 5. An exploratory operation, even in a patient seriously ill with a localised tumour in the region of the gall-bladder, is worth advocating, as though malignant disease may be feared, the disease may be only inflammatory and therefore capable of relief. 6. If there are any secondary nodules in the liver, or if adjoining viscera are seen to be invaded, the operation had better be no more than exploratory.

Mr. MORTON asked if it were possible to examine the whole liver from the wound.—Mr. ROBSON, in reply, said it was quite possible to examine the whole of the surface of the liver, and in reply to a question from Dr. Roberts he explained that if he thought drainage necessary he used a large rubber tube with gauze inside and he placed it in the "right kidney pouch."

Dr. H. G. RAWDON (Liverpool) read a paper on two successful cases of Enterectomy following strangulated hernia, in which Murphy's buttons were used. In each case many inches of bowel were excised, the button was readily adjusted and recovery was speedy and complete. In one case the button was never found though often looked for.

Perforation of Gastric Ulcers.

Mr. J. P. BUSH (Bristol) gave an account of two cases of Perforation of Gastric Ulcer, in which he performed laparotomy. The operation in the first case was done twenty-six hours after perforation and the patient did well for three weeks and then died suddenly, probably from cardiac syncope. The other case, operated on eighteen hours after perforation, recovered completely. In each case he sponged the peritoneum, but did not wash out.

The PRESIDENT expressed his opinion that sponging might be sufficient in cases treated soon after the perforation, but he thought irrigation was needed for those seen later.

Mr. THOMAS H. MORSE (Norwich) had had four cases and only one died and that one was operated on twenty-four hours after perforation. He thought irrigation was less harmful than sponging.

Dr. W. WHEELER (Dublin) thought that irrigation with a saline solution was the best method of treatment.

Dr. MACLAREN (Carlisle) said that the after treatment of perforated gastric ulcer was still in the experimental stage. He considered the chief conditions of success were the strength of the patient and the thorough cleansing of the peritoneum.

Surgical Treatment of Empyema.

Dr. MENZIES HUTTON (Edinburgh) read a paper on the Treatment of Empyema. He expressed the opinion that, though aspiration might be sufficient in children, incision and drainage was the best treatment at all ages. To enable the lung to expand he had devised a valved drainage tube which permitted air to pass out on coughing or expiration, but prevented its return. Good results had followed its employment, in one case even eight months after the incision. The only condition in which this tube should not be used was when a bronchus opened into the empyema.

Mr. J. H. NICOLL (Glasgow) described his operation for Chronic Enlargement of the Prostate. He removed by means of special forceps through a perineal wound portions of the enlarged gland, without injuring the urethra or bladder, so that the risk of septic absorption was much diminished. During the operation the prostate is pressed down from above by the fingers introduced through a suprapubic cystotomy wound. The results had fully justified the operation, and when the doubtful benefits of castration and vasectomy were considered, he thought the operation was deserving of an extended trial.

OBSTETRICS AND DISEASES OF WOMEN.

WEDNESDAY, JULY 27TH.

The Presidential Address in this Section was delivered by Dr. A. R. SIMPSON, Professor of Midwifery and Diseases of Women and Children in the University of Edinburgh, the subject being

The Teaching of Obstetrics.

Dr. Simpson commenced by mentioning that the chair in the University of Edinburgh was the oldest midwifery chair in existence, history showing that when the Town Council of Edinburgh instituted in 1726 a professorship of midwifery in the University they unwittingly established a precedent. He went on to claim that midwifery, though late in development, had now come to rank with medicine and surgery in importance, while its constancy of recurrence rendered it the most important part of the general practitioner's practice. "I try to get students to believe," said Professor Simpson, "that the successful conduct of confinements is the surest guarantee for speedy success on their entrance on the career of an ordinary practitioner. Coming into a locality a young doctor may get a reputation in the community for managing well an outbreak, say, of typhoid fever or for operating well in some case of injury. But his very triumph over the typhoid has only been complete when he has succeeded in preventing the possibility of its recurrence, and people will not be less careful to protect themselves from injuries though they know they have a skilful surgeon near at hand. But each time it is whispered among the ladies that he is specially skilful in the handling of his confinement cases the rumour of his skill and kindness must fall on the ear of someone who will say to herself: 'My time is coming; I must have him to attend on me.' It is the only gate into general practice that is always open everywhere. Men who have gone through a medical curriculum with the bare modicum of midwifery which may carry them past a final examination have afterwards found themselves in a situation where they might have rendered good service to a suffering fellow creature if they had not been in a hurry to forget what little they had learned. I have heard a gentlemen who had attained to eminence tell how during his student course he had imagined that all he needed earnestly to study was surgery, as he was destined for the Army Medical Service; but, to his horror, he found that the first professional service he was called upon to render on board a troopship was to deliver a soldier's wife, a service in which he was glad to avail himself of the efficient help of a skilful matron who was on board. A practitioner may see a case of diabetes once in two or three years; or he may have a run of cases for a time and then for years fall out of acquaintance with it. So with many other forms of disease; they may come and they may go from the visiting list but the midwifery cases go on for ever. So long as the practitioner has his place by the side of the river of life watching its menstrual ebb and flow and prepared to render efficient aid he will find it float confinements to his charge with the steadiness of the tides. Moreover, there is this to be said in regard to deliveries, that whilst the ordinary run of them are cases of natural labour which may not call for active intervention, at any moment emergencies may arise which will tax to the uttermost the practitioner's resourcefulness and self-reliance. If he has a case of heart or lung or brain disease which leaves him undecided when he sees it first as to what should be the best line of treatment,

Digitized by Google

he can probably prescribe something that will be useful, or at least not hurtful, until on a second visit the course becomes more clear or until he has had time to read up the subject in a system of medicine. If he cannot at once classify a skin disease, the case will not go wrong whilst he compares it with the plates of some work on dermatology. If he does not feel quite sure what kind of truss to order for a hernia he can politely propose to give the instrument-maker instructions about it and in the interval refresh his memory at some surgical source. In most of the difficulties in ordinary practice the family attendant may even, if he see fit, call in the aid of a consultant. Their combined wisdom may make for the recovery of the patient or, at the worst, give the patient and the friends the comfort of thinking that everything had been done that could be done. But if a man comes to a midwifery case and finds an arm protruding it is too late to think of reading up his Playfair; if at the end of a labour which has gone on smoothly he finds his patient become pale and pulseless he has no time to get assistance. Before help can come the flooding may be fatal. If he is not to see the patient die before his eyes he must recall the measures he has been taught to adopt in this contingency and he must apply them with his own hands immediately. I am persuaded that every member of the Association present will bear me out when I thus intone the prime importance of this department in a doctor's daily round. But as you cast your minds back to your student days how does this predominance of midwifery in your practice look in comparison with the little time devoted to it in your classes? The obstetric teacher among a company of physicians and surgeons is apt to find his subject regarded as a kind of subordinate speciality which may be lectured on at any odd time to senior students whose best hours are all laid out for them in the interests of systematic and clinical medicine and surgery and their subsidiary branches. It has always seemed to me that this is to do an injustice to men whom we profess to send out fully qualified to undertake all the duties of a medical practitioner. It is altogether out of proportion to have them, as they commonly are with us, under the necessity of attending two six-months' courses of systematic surgery and three three-months' courses of clinical surgery, whilst, apart from the gynæcology they learn in connexion with clinical medicine, all the midwifery that is enjoined on them is the six months' systematic course, three months of clinical teaching in the maternity and attendance on six cases of labour. This gives them a false impression of the work which lies before them and implies superfluous attention to surgery or inadequate instruction in midwifery. I would not have the surgical discipline diminished, but, surely, men should not be sent out to practise their midwifery with only half the training which they have enjoyed for their surgery. A fifth year was added just a lustrum ago to the medical curriculum. It was understood to have been added in the interest of the practical subjects of study, but I protest that, in Edinburgh at least, the student has lost rather than gained in his opportunities of qualifying as an accoucheur in consequence of the changes which have been made for the more prolonged curriculum. Examinations in some of the scientific subjects are such that many men find themselves compelled to take two systematic courses as well as the compulsory practical course to enable them to pass, so that not only the first three years are swallowed up, but generally the fourth as well, before they can at all face the subjects of their final examination and then the time that remains is so largely claimed for medicine and surgery that midwifery runs the risk of being driven to the wall. It has sometimes been suggested that a greater security for proficiency in midwifery would be given by making it compulsory on candidates for diplomas to have attended a larger number of cases during their curriculum than has hitherto been required of them. This, I am convinced, is a mistake. The attendance on a case of labour is not like a visit to a dispensary patient. It cannot be done in the course of an afternoon walk. It means the occupation of hours—it may be of a whole day or a whole night. And the young fellow, already overburdened with work, is to spend these hours or days or nights twenty times over in the slums! No; it is not fair. And it is futile. What guarantee does a man's attendance on a score of confinements give of his knowledge of practical midwifery or of his fitness to deal with difficult cases? There may have been some tedious labours among those he witnessed. He may even have had the exceptional luck to see forceps applied. He counted himself most fortunate when he arrived just in time to see the infant washed; or he became a hero because he lighted on a cross-birth where he sent for the house-surgeon to turn, and the house-surgeon had to send for the physician to decapitate. But all that does not make him fit to cope with the first complication that may meet him in his own practice afterwards. What is needed is that arrangements should be made for the student to have a full winter course of systematic study of midwifery after his intellect has undergone the discipline of the earlier scientific subjects and his mind is free from the incubus of the examinations which followed. His teacher should have the opportunity of fully expounding to him the many dangers and difficulties which he must be prepared to encounter and of explaining to him the methods by which these may be most successfully combated. In connexion with this course he will be drilled in the use of the various obstetric and gynæcological instruments and appliances, and especially he will be practised in the application of forceps and in the operation of version on the phantom. Phantom courses should be regarded as an essential part of the student's training. Practical gynæcology ought to constitute a part of his clinical medical discipline and an element in his clinical examination. As for the practical midwifery, in addition to the attendance under superintendence of a qualified practitioner on a limited series of cases—of which he should present a detailed record—he ought to attend the cliniques in a maternity hospital."

STATE MEDICINE.

WEDNESDAY, JULY 27TH.

Sir HENRY LITTLEJOHN, in opening this Section, complimented the members on the presence for the first time of ladies. In the 1875 meeting of the Association as medical officer of health he was dealing with the housing of the working classes. A special Act was afterwards passed and £560,000 were expended in carrying out its provisions. In three or four years there was a marked influence on the death-rate—many of the town councillors expected an immediate fall in the rate. The mortality had fallen from 28 per 1000 to 17 per 1000 for the last five years. Those figures represented the total mortality and to that extent involved a fallacy. Edinburgh has its plague spots, such as, for example, the Cowgate and the Grass-market, where the rate touched 30 and 33 per 1000. Another great subject before the meeting in 1875 was the question of drainage. By reference to maps the growth of Edinburgh was demonstrated from 1620 to the present day. In 1875 the Water of Leith was nothing more or less than an open sewer. Parliament, however, compelled the town to carry out the sewage and discharge it into the Forth. The effluent pipe was made too small, and only within the last five years had a pipe of sufficient size been inserted to carry off sewage and storm-water. At the same time the refuse of paper and other factories was diverted along with the drainage of sundry villages. Fish now flourished in the Water of Leith and the question of drainage was satisfactorily settled so far as the New Town was concerned. The drainage of the south side of the town was diverted from the Powburn and discharged into the Craigentinny irrigation meadows, the rental of which is now £18 per acre, and was formerly £40. In 1875 an interesting addition to the water-supply was in contemplation. The Pentland Hills watershed was drained and a fresh supply was sought from the Lammermoors. To keep up the supply of 38 gallons per head Edinburgh had to go to still other watersheds and a stream, the Talla, had been impounded. A population of 296,000 was supplied nominally, but really it included some 400,000 in all. The Edinburgh system of sewage removal began under difficulties. When many years ago he took the late Dr. Parkes into some of the old tall houses of the town he said he would call them "not houses but upright streets." The system of ashes and refuse removal was in full force in Edinburgh and the inhabitants had been educated up to it in this respect. In 1875 2*s.* 9*d.* per ton were given by the farmers for solid refuse; now the farmers would not take it at any price. The introduction of water-carriage deprived the refuse of its manurial value; now they had built a destructor. In 1875 there was no Notification Act, but the Act was soon afterwards introduced; at that time the proposal was almost universally opposed by medical men, including the Royal Colleges. It passed, however, in the hurry of an

Digitized by Google

omnibus Bill. In one year near that period 6000 cases of typhus fever occurred and many medical students and men died from the disease. Now that disease had been practically wiped out by the clearing away of rookeries and by notification. Sporadic cases occurred, but the disease was now as fatal and virulent to this day as ever in Edinburgh. The infectious hospital was located in the old High School, a place of classical association. The hospital was fixed in the poorest site in Edinburgh, but there was no spread in the *entourage*. Small-pox was not treated there, but he (Sir Henry Littlejohn) did not believe that aerial spread of that disease took place, at any rate to any extent, with ordinary care.

Rivers Pollution.

An interesting debate on this subject was then opened by Dr. M'LEAN WILSON, in which Professor GLAISTER, Dr. BRUCE LOW, and Dr. J. C. MCVAIL, among others, took part.

PSYCHOLOGY.

WEDNESDAY, JULY 27TH.

The proceedings in this Section were opened by the President, Dr. T. S. CLOUSTON, physician-superintendent, Royal Edinburgh Asylum and lecturer on mental diseases in the Edinburgh University, who took as his theme

The Neuroses and Psychoses of Decadence.

In 1890, he said, I directed attention to that series of nerve disturbances and diseases occurring early in life which might properly be grouped together under the heading of "The Neuroses of Development." To-day I desire to make a few suggestions which will point to another series in which would be included a considerable number of the nervous and mental diseases and disturbances which occur in the later periods of life, and which might, I think, be properly grouped as "The Neuroses and Psychoses of Decadence." The one series all have as their chief and often their only cause faulty development of nerve centres; the other series have as their predisposing cause unphysiological decadence of brain and nerve. In the former series a neurotic heredity is always present; in the latter it is not necessary. In the former series there need not necessarily exist any exciting or proximate cause; in the latter such exciting causes as toxic agencies in the form of syphilis or alcohol, the effects of hard work or unphysiological conditions on the brain extending over many years, worry or strain, the access of the climacteric or senility are commonly present. In the former class the strain of taking up new functions, especially the all-dominating one of sex and of the reproduction of the species, has upset or arrested nervous development from an inherent weakness of power to produce a sound, strong fabric of nerve centres; in the latter the breakdown is not due only to the cessation of reproductive energy, but commonly to want of staying power of the centres to do the work imposed on them or the want of resistive power against undue strains or poisons. The most of developmental neuroses may in one way be looked on as Nature's effort to stop a bad stock before it reaches the time to reproduce itself. Man's normal, average life may be divided into three periods of twenty-five years each. During the first quarter of a century his body is growing and his functions are maturing, the last organ to attain physiological perfection being the brain cortex. During the next period the fullest muscular action, the highest resistive power against disease, and the most reliable and intense mentalisation are found. During the last period a slow process of retrogression and decay sets in and goes on till the physiological ending of death is reached. As during development one organ or function may lag behind its normal maturation time in reaching perfection thus constituting a neurosis from unrelational development, so during decadence every physician and every alienist has had experience of a premature decay in individual organs and functions, constituting a neurosis through unrelational decadence. One man's trophic energy fails at fifty-five, and he then loses 3st. of flesh and falls a victim to the first severe bronchial catarrh that attacks him. The cardiac innervation of another fails at sixty and influenza cuts him off. The memory of another quite gives way at sixty-six, while another loses originating volitional power at seventy, so that he cannot then manage the simplest business. Then the cessation or slackening down of the great reproductive energy at the climacteric period in both sexes is attended by such frequent nervous and mental disturbances that in their lesser degrees they are commonly regarded as rather normal than abnormal in their character. There are low forms of animal life which terminate their existence with reproduction. Continuation of the species with them is death to the individual. There is no intermediate sexless barren zone between fecundity and death, as in man and most of the higher animals. A period of slower ebbing of life—of decadence in fact—in the latter takes the place of the absolute termination of existence of the former, but the whole barren period becomes subject to many diseases and defects that are incidental to this period. The last epoch of all, that of vascular disease and imperfect blood-supply, and demonstrable nerve cell and fibre degeneration, is one necessarily attended by many neuroses and psychoses. Then it is that senile endarteritis, fatty vessels, atrophies, apoplexies, softenings, senile dementia, with irritative mechanical states superadded, come on. It is the time, too, for the more partial breakdown of muscular weakness and incoördination, senile amnesia, senile irritability, senile paralysis of family and natural affections, and senile immoralities. Though bad heredity does not come in so powerfully in decadence as during development it does operate in some cases and thereby brings on decadence or disease before their time. A glance at the general statistics of the neuroses and the ages at which they prove fatal conveys some idea of how they are related to the periods of development and decadence. Taking the report of the Registrar-General for Scotland for 1895 we find that there are 55 per cent. of the population living between one year and twenty-five years, both inclusive—that is, during brain growth and development. The number of deaths from diseases of the nervous system during this period amounted to 3262 out of the total of 9307, or 35 per cent. At the next period, that of full strength, from twenty-six to fifty years, the proportion of the population alive was 30 per cent., while the proportion of deaths from the neuroses sank to 12·2 per cent. In the next period, when decadence has begun, from fifty-one to seventy-five years, the proportion alive was only 12 per cent., while the proportion of the fatal neuroses rose to 33·2 per cent.; and the last period, from seventy-six to one hundred years, that of marked senility, showed only 3 per cent. of the population alive, while 14·8 per cent. of the deaths from neuroses occurred then. The conclusions from this comparison of figures are that the neuroses prevail largely in the period of brain growth and development of function (the detailed statistics for each year show that the first two years are very deadly neurotic years), that the very best years of life are very free from them, and that decadence brings them on with a rush to a far more deadly degree than even during development, senility being the most deadly neurotic period of all. The functional nervous explosions of convulsions are the most deadly of the developmental neuroses; the organic vascular-neurotic destructive lesions of apoplexies and brain softenings kill most frequently after fifty years. Looking to the prevalence of the insanities of development and those of decadence I find that about 12 per cent. of the whole number of new cases occurring each year may be put down to development, not including idiocy and congenital imbecility. If these are included bad brain growth and development account for about 40 per cent. of the whole existing insanity and weak-mindedness in the country. On the other hand, decadence (climacteric, senile, and paralytic insanities) accounts for about 20 per cent. of the insanity and 5 per cent. of the combined insanity and idiocy of the country. At least our statistics at the Royal Edinburgh Asylum over twenty years give these results. We shall not be able to put on a really scientific basis the diseases of decadence until we know the exact steps in the normal process of decay of structure and function in every tissue and organ. The great regulative action of the higher cortex on the nutrition of all tissues and on the function of all organs undergoes a steady deterioration as age advances. The whole body shrinks in volume, except the less organised fat cells in some cases. No doubt it is owing to this fact that there is a less general resistive power in the organism to certain diseases from within and from without. Rheumatism and gout become chronic, bronchitis kills off its victims after sixty years by the 100,000, and neoplasms then become more numerous. The enemies of the tissues and of the organism get too strong for them. During all this process of decadence of the higher nerve centres it is not surprising that diseases and disorders special to the period should appear—namely, the true psychoses and neuroses of

Digitized by Google

decadence. The different ways in which a decadence affects the resistive quality of the brain and spinal cord against nerve toxins is, I think, best illustrated by studying a number of alcoholic cases past the prime of life and correlating their symptoms—mental and bodily—with their ages, their heredity, their occupations, and their habits in youth. We have all had experience of the immense variety in the alcoholic neuroses and psychoses in different cases according to whether the patient was in mid-life or beyond fifty years. The most common case is that in which a man has taken alcoholic stimulants freely but not to manifest excess from his youth and they have had no appreciable mental or bodily effects till he reaches the age of forty-five or fifty years, when all at once, within two or three years, his eye and face get bleary, his hair gets grey, his hand gets shaky, his memory and acuteness of mind fail, his force of character lessens, his morals deteriorate, his weight either goes up by the deposition of useless fat or drops a stone or two through lack of trophic energy, his walk changes so that he no longer has a firm "grip of the ground," and he looks twenty years older in these two years. What has happened? The chief thing, I think, has been that his nerve centres—mental, motor, and trophic—have suddenly lost their resistive power against the alcohol, and its full toxic effects on their functions have thus become apparent, and this because commencing decadence has begun and altered the quality, structure, and energising of his neurons. A parallel series of clinical facts can be observed in regard to syphilis and lead poisoning. We have three chief types of nervous and mental lesion connected with decadence. The first consists chiefly and primarily of a vaso-trophic degeneration, through which the cerebral vessels first lose their elasticity and then gradually their walls take on various trophic changes and degenerations generally or in patches, when in the course of their constant expansions and contractions as more or less blood is called for by the neurine, they can no longer sustain the blood-pressure and they burst. This is the cause of the vast mass of the destructive brain lesions, the softenings, the apoplexies, which bulk largest as the causes of death in the registrar's returns. No doubt the chief degenerations of the vascular coats are the atheromatous, the inflammatory (senile endarteritis), and the hyaline. It cannot be doubted that the brain tissues regulate by innumerable vaso-motor centres their own blood-supply and there can be as little doubt that the nutrition of their walls is also regulated from centres in the brain. No doubt in most cases of apoplexies from vascular disease we have also some amount of surrounding nerve degeneration. There is a solidarity throughout the whole brain, through which a tissue change seldom occurs in one organ, or system, or centre, or envelope without some amount of pathological change in some or most of the others. The second typical lesion of decadence seems to me to be best represented by those degenerations of the motor and sometimes sensory systems which constitute the ataxies, the scleroses, and the other progressive degenerations. The third typical series is constituted by the mental disturbances and diseases grouped under the climacteric and senile insanities. In them undoubtedly the primary lesions begin in the mental tissues and mental areas.

PATHOLOGY.

WEDNESDAY, JULY 27TH.

Professor GREENFIELD, the President, having said a few words of welcome to those attending the proceedings of this Section, Dr. ROBERT MUIR opened a discussion upon

The Nature and Significance of Leucocytosis.

After referring to the importance of the subject and its wide range, he said that he would confine his remarks to leucocytosis as a process in general pathology and more particularly to the fundamental changes on which the excess of leucocytes depends. A general leucocytosis may occur in many acute inflammatory conditions, especially if suppurative; and experimental leucocytosis may be produced by the injection of various substances, especially bacterial products. There can be little doubt that in such cases there is an actual increase in the total number of leucocytes, not simply an accumulation in the peripheral vessels. This view is supported by the observations of Goldscheider, Jacob, and many others, and also by the fact that in conditions of suppuration there is an enormous emigration of leucocytes, so that several ounces of pus may be discharged daily while the number in the blood continues in excess. Where there is such a continuous drain and at the same time an excess in the blood the production of leucocytes must necessarily be greatly increased. The sites of origin of the different varieties of leucocytes is a point on which sufficient stress has not been laid. First, leucocytes multiply by mitotic division in adenoid tissues, lymphatic glands, Malpighian patches of spleen, &c. These leucocytes are small spherical cells with a relatively large nucleus and scanty hyaline protoplasm. Secondly, leucocytes undergo division by mitosis in the bone-marrow. The great majority of the cells dividing these are of somewhat larger size and their protoplasm contains fine granules which have an oxyphile or neutrophile reaction. Eosinophile cells also multiply in the marrow, but they are fewer in number and their division is less active than the former variety. Now, in the blood there are no cells with a simply spherical or oval nucleus and finely granular protoplasm like the finely granular cells in the marrow. Further examination of the marrow shows that these cells present great variation in the configuration of the nucleus, that, in fact, one can trace all the intermediate stages from the simple rounded or oval nucleus through various degrees of lobulation to the markedly multipartite nucleus and the finely granular, actively amœboid leucocytes. According to this view these cells, after division in the marrow, undergo a change in the nucleus which specially adapts them for amœboid movement, and in this fully-formed condition they enter the blood. If the above conclusion is justified, then important changes should be found in the marrow when there is a constant drain on this variety of cell. A considerable number of experiments were undertaken with this object in view. Artificial leucocytosis, or at least a removal of leucocytes from the blood, was produced by subcutaneous or intraperitoneal injections of organisms, chiefly staphylococci. The experiments lasted for various periods of time up to four and a half weeks. Striking changes were found in the marrow. The fat cells become absorbed and the cellular elements undergo a corresponding hyperplasia. The cellular increase is due to excessive production of the finely-granular leucoblasts which are the source of the finely-granular leucocytes of the blood. The coarsely-granular eosinophile cells are relatively, and it may be absolutely, diminished. Erythroblasts or nucleated red corpuscles are also much diminished. The giant cells undergo degenerative changes and in great part disappear. This leucoblastic type of marrow corresponds to the erythroblastic type which is found after hæmorrhage. This fact appears to be of great importance, for in any case of suppuration there are (1) locally an enormous number of finely granular leucocytes (pus corpuscles); (2) in the blood a great increase in number of the same cells; and (3) in the marrow a great increase in the cells from which these leucocytes are derived. Further, it is very probable that the same cause will explain all these phenomena. Bacterial products act as chemiotactic substances, and if in small quantity may produce only local suppuration without leucocytosis. If, however, the suppuration be more extensive, then these substances which produce chemiotaxis are absorbed in such quantities as to act on the leucocytes lying at the periphery of the blood-channels in the bone-marrow and so produce a general leucocytosis. The increase in the number of finely granular leucoblasts is probably due to a direct stimulating effect which these substances exert on them. This view very closely corresponds with that which Ehrlich has adopted in his latest publication, but these conclusions were reached quite independently and the changes in the bone-marrow have not previously been described. Dr. Muir then showed an interesting series of lantern slides from photo-micrographs in illustration of his experimental work in leucocytosis.

Professor GREENFIELD congratulated Dr. Muir on his able exposition of the subject and said that his results threw enormous light on the pathology of leucocytosis.

Professor HAMILTON said that in his opinion many cases of leucocytosis were not due to a general increase of leucocytes but merely to an accumulation in the peripheral vessels. As regards the cause of a general leucocytosis, granted that it did occur—e.g., from injection of various substances or organisms—he said that the usual explanation was the theory of chemiotaxis. He deprecated any dogmatic statement on such questions and suggested as a possible explanation that bacterial poisons stimulated the lymphatic glands to throw off

Digitized by Google

more leucocytes just as certain drugs stimulate the liver to increased secretion. He then discussed the phagocytic action of leucocytes.

Dr. EDMONSTON CHARLES (Rome), said that in Malta fever he had found that the polymorphonuclear leucocytes were quite absent from the blood, and only lymphocytes were present. In other fevers, on the contrary, there was no such absence of the polymorphonuclear cells. The great importance of this to the physician was due to the fact that it afforded him a rapid method of diagnosis between typhoid fever and Malta fever. The sedimentation and agglutinative tests were of great value, but could not be undertaken by the ordinary physician. In further illustration of the importance of clinical examination of blood-films he said that in appendicitis the date at which a patient might get up could be told with almost absolute precision. If leucocytosis was present, then the patient should on no account rise even in the absence of all other symptoms; but if the leucocytosis had subsided, then, even in the presence of other symptoms, the patient might get up. He concluded by quoting a case in which the observation of a polymorphonuclear leucocytosis had enabled him to predict the onset of an acute pleurisy twenty-four hours before the physical signs appeared.

Dr. WOODHEAD agreed with Professor Hamilton that theories can at present serve only as working hypotheses, but he thought that Dr. Muir's paper would be of great assistance in forming definite conclusions on this subject. The great importance of his paper lay in the fact that two sets of cells were localised: (1) a series of changes in lymphatic glands and their effects on the blood; and (2) a series of changes in the bone-marrow and their effects. The theory of chemiotaxis might now be more accurately studied when the sites from which the various cells came had been more precisely localised. Similarly, phagocytosis could be more satisfactorily investigated, since the irritant could be applied at special sites.

Dr. LAZARUS BARLOW contrasted the present state of knowledge of granular-celled leucocytosis with that of non-granular-celled leucocytosis, and maintained that the former was the more advanced. He regarded granular-celled leucocytosis as a process of the same nature as that which leads to the appearance of granular cells at the site of an inflammation. The question of non-granular-celled leucocytosis was much more difficult, chiefly because of the uncertainty which prevailed concerning the nature of the cells involved. Lymphocytosis probably depended simply on a washing out of the adenoid tissues during digestion, but where there was an increase of the large hyaline cells then it was uncertain whether they were enlarged lymphocytes or endothelial cells, or fibroblasts, or even cells of a lympho-sarcoma.

Dr. DURHAM said that the bone-marrow was a tissue comparatively neglected, and strongly urged its routine examination in all organismal conditions. In some cases of bacterial infection—e.g., in Malta fever—he had found the organisms present in the marrow though all the other organs and tissues were sterile. He also discussed the resolution of artificial leucocytosis when the number of lymphocytes in the blood is in excess of the normal. He had never seen any transitional forms between the polymorphonuclear leucocyte and the lymphocyte, and suggested that the latter was probably more sluggish in disappearing. He concluded by emphasising the extreme rapidity with which these changes occurred in the blood and in all the cavities of the body after experimental leucocytosis, and said that these were consistent with the changes in the leucoblastic bone-marrow which Dr. Muir had described.

Dr. MILROY said that in the experimental leucocytosis caused by the injection of nucleic acid there was an alteration in the ratio between the amounts of nitrogen and P_2O_5 excreted compared with that in health. There was, indeed, both an absolute and a relative increase of the excretion of P_2O_5. On the other hand, in medullary leucocythemia the excretion of P_2O_5 was both absolutely and relatively diminished as compared with the nitrogen and he suggested that this fact seemed to imply some check in the normal disintegration of the leucocytes.

Dr. COPEMAN and Dr. GRÜNBAUM also spoke.

PHARMACOLOGY AND THERAPEUTICS.

WEDNESDAY, JULY 27TH.

The President of this Section, Dr. J. O. AFFLECK, Lecturer on the Practice of Physic and on Clinical Medicine in the Edinburgh Medical School and Physician to the Edinburgh Royal Infirmary, opened the proceedings of the Section by delivering the short Presidential Address which follows entitled—

The Progress of Therapeutics.

The subjects included in this Section can never cease to be of interest to those engaged in the practice of medicine or fail to occupy a prominent position in the business of a congress like this. However widely diverse the topics dealt with in our proceedings here there may be traced through them all a certain unity of purpose and a common object towards which they converge—the treatment of the sick and suffering. Doubtless many points relating to treatment in individual diseases are fully discussed in other sections, but it seems nevertheless an advantage that there should be a department in which therapeutics and our therapeutic resources are specially considered, and towards which some will naturally turn in the hope of gaining or of imparting information. The conjunction of the two subjects of pharmacology and therapeutics necessarily makes the field in this Section a wide one; but it has the obvious advantage of bringing into contact for discussion those specially skilled in the knowledge of the composition, properties, and actions of medicinal agents and those whose main duty lies in practically applying these in the daily work of their profession. Having myself more in common with the latter category, I do not propose in this brief address to dwell upon any subject in the domain of pharmacology, even had time or ability admitted of my doing so. During the twenty-three years which have elapsed since the last meeting of the Association in Edinburgh the number of new remedies has been multiplied enormously, chiefly by the adoption as therapeutic agents of substances which organic chemistry has so richly provided, the virtues of many of which are beyond all doubt. An illustrative instance might be cited in the power of salicin and salicylic acid and its compounds to lessen the pain, and in many cases to shorten the attacks, of acute rheumatism. The groups, too, of synthetic analgesics, antipyretics, and antiseptics have furnished us with substances which (while requiring at all times care and judgment in their selection and administration) are among the most widely employed and efficacious of the resources for treatment placed in the physician's power. Conspicuous among the therapeutic advances during the period have been the large number of remedial measures which lie outside of the materia medica and which—many of them at least—are eminently rational in their conception and application. The developments of pathology and more accurate clinical methods have contributed in no small degree to bring about this result. A therapeutic measure of immense value is the method of treating stomach disorders by lavage, a plan which owes its origin to Professor Kussmaul, who originally designed it for use in dilatation of the stomach, but which has since been extended to the treatment of many other painful conditions of digestion to which it can oftentimes bring marked relief. A better acquaintance with the processes of the gastric chemistry, too, has been turned to useful account in the various methods of peptonising foods in cases of dyspepsia. An entirely new field of therapeutics has been opened up by antiseptic surgery, and some of the most formidable and fatal of all maladies which were at one time regarded as outside the reach of remedies have been made possible of cure. This has been especially the case as regards the abdominal cavity, where the wall of partition which divided medicine and surgery has been broken down and conditions of disease formerly believed to be hopeless are now successfully dealt with by surgical operation. The gynæcologists led the way in this direction. Many cases of acute peritonitis which thirty years ago were treated only by opium are now explored surgically, and, whether due to the perforation of a viscus, disease of the appendix vermiformis, or acute intestinal obstruction, are cured by the timely intervention of the surgeon. Excision of the kidney and operations upon the liver, the stomach, and the intestines are now common occurrences, and many a life is preserved and much suffering spared by these modern methods of treatment. Indeed, it sometimes happens that cases which on exploration were found to be beyond the reach of radical treatment may yet by this very operation be materially benefited as regards some of their distressing symptoms. The surgery of the brain, at one time deemed a practical impossibility, has yielded, especially in the hands of Professor Macewen, results which have arrested the attention of the whole world of medicine.

Digitized by Google

The employment of massage as a therapeutic agent has been found to be a valuable adjuvant in the treatment of various forms of paralysis, particularly those of peripheral origin; in many functional disorders of the nervous system; in the disabling sequelæ of rheumatism; in certain varieties of dyspepsia; in insomnia; and in the debility of convalescence. The amount of aid to be obtained from electricity as a therapeutic measure is not to be gauged by the comparatively limited extent of the results hitherto obtained by its use. Its more recent developments seem to promise for it a wider sphere of useful action as a means of treatment. The employment of various forms of baths in the treatment of disease has until recent times held a much less prominent position in this country than on the continent. But their value is now gaining much wider and more practical recognition. The application of regulated exercises in the treatment of heart disease by the Oertel system or by the more recent Nauheim method has been found to yield excellent results in many conditions of cardiac enfeeblement with or without valvular disease. Nevertheless the range of applicability of this form of treatment is probably less extensive than some of its more strenuous advocates contend, and at all events much care and discrimination are called for in the selection of presumably suitable cases and vigilance in observing the effects lest harm result. The open-air treatment of phthisis in specially constructed sanatoria has recently awakened widespread interest. This method, which seems to rest upon a scientific and rational basis, is still but upon its trial, yet results of an encouraging kind have already been obtained. Of no less importance, and with a still wider range of beneficent result, are the means which bacteriological investigation has placed within our power of identifying specific organisms in infectious diseases and observing their life-history and toxic properties. The way has thus been opened for the scientific study of immunity, and this again has resulted in the discovery of protective and curative antitoxins, of which that of diphtheria is the most outstanding example. The testimony which has been borne to the value of this treatment in that dreaded malady has been universal. Others of the deadly scourges of humanity are now also being effectively combated by serum therapeutics. For this work we are indebted to the Pasteur Institute, where also the anti-rabic treatment of hydrophobia was discovered by its famous founder. It would be impossible in any sketch of therapeutic advance to omit a reference to the growth and development of the modern system of nursing the sick. The work of setting apart properly equipped women as nurses, with which the name of Miss Nightingale will ever remain associated, has had the effect of revolutionising to a large extent hospital treatment, has incalculably contributed to the relief and comfort of sufferers, and has lightened the labours and anxieties of medical men. Outside of hospitals, throughout all classes of the community the benefit has been no less conspicuous. The beneficent work of nurses is universally recognised and appreciated by the public and is happily now made available for the poorest of the poor.

OPHTHALMOLOGY.

WEDNESDAY, JULY 27TH.

Dr. ARGYLL ROBERTSON, the President of this Section, in opening the proceedings of the Section, began by thanking the members for the honour they had conferred upon him by electing him President, and expressed the wish that it would be a most profitable meeting, and said that he would do all that lay in his power to make it such. He briefly touched on some of the more important advances that had been made in ophthalmology during the past year, the intra-oculous injections in various forms of septic conditions, and the treatment of corneal opacities. He also pointed out that further investigation was required in the treatment of glaucoma and detachment of the retina. The department of ophthalmology had developed in importance with great rapidity during the past 40 years; at that time there were only two ophthalmic surgeons in Scotland as compared with the large number that abound at the present time. This is largely due to the necessity of the correct treatment of refractive errors. Such things as cylindrical lenses were unknown in those days, but as a result of the labours of men such as Donders, Snellen, and others the state of affairs has very much altered. He then referred to the subject of examinations in ophthalmology for final students. He stated that a great deal had already been done, especially in Dublin, but still a more thorough examination should be insisted upon. The President then closed his remarks by thanking those distinguished men who had come great distances to read papers at the meeting and honour the Association with their presence.

The PRESIDENT then called upon Professor Nuel to give his paper on

Absorption of Aqueous Humour by the Iris, with Specimens and Lantern Demonstration.

Professor NUEL (Liège) commenced his remarks by stating that he had experimented on rabbits, cats, and dogs, and with the aid of microscopical sections illustrated his theory of absorption. Indian ink solution was introduced into the anterior chamber and the effect watched by making section of the iris and ciliary body some hours afterwards. He found that the lymph-channels in the iris of the rabbit are rudimentary, whereas those in the cat and dog are well developed, especially towards the peripheral zone of the iris, those near the pupil being smaller and further apart. When a solution of Indian ink is introduced into the anterior chamber these channels take up the black pigment which is easily demonstrated by microscopical sections. In a few days the pupil becomes dilated and obliterates these lymph-channels. The presence of Indian ink sets up an inflammatory reaction in the iris which extends to the ciliary body. In successful cases this Indian ink penetrates as far as the blood-vessels in the course of six or eight hours; it also extends towards the pupil, accompanied by a deposit of a large number of migratory cells. In one case of a dog a section was shown where the pupil had not dilated and the Indian ink was well marked along the line of the blood-vessels. With a *résumé* of these cases Professor Nuel concluded his remarks.

Mr. GEORGE BERRY asked whether Professor NUEL was of the opinion that extensive absorption took place in the iris? He pointed out that in septic cases as a result of injury absorption takes place from the anterior surface of the iris more than from the canal of Schlemm and the angle of the iris. In reply Professor NUEL stated that it was his opinion that absorption took place more on the anterior surface of the iris than from the other parts mentioned.

Dr. THOMAS REID then gave a lantern demonstration illustrating the reparative processes in the cornea. The specimens shown were the result of many years' investigation on the reaction of the cornea after severe stimulation. The first case showed the edges of the wound in the cornea turned in with complete union of the epithelium over them. The next case showed the epithelium extending over the prolapsed iris in the course of 24 hours after the accident. The next was one of gunshot wound 24 hours after the accident showing total destruction and failure of the epithelium to bridge the rent. Another case demonstrated a rupture of the cornea with ragged edges with the epithelium extending over the corneal tissue; on the third day after the accident in this case the columnar cells were more active than they are usually supposed to be. Several cases were then shown illustrating the appearances of lacerated wounds in the cornea. Other cases were shown, one demonstrating union in a more or less perfect state 15 days after the injury, with a proliferation going on to form corneal tissue. He then showed cases of superficial lacerated wounds with the epithelium extending down into the cavity within a week after the accident.

Dr. GEORGE MACKAY and Dr. J. C. DUNLOP related a case of

Acquired Complete Colour-blindness

(with specimen). The case was read by Dr. Dunlop. The patient suffered from cancer of the stomach. He suddenly lost the colour sense; every colour appeared as grey; there was no word-blindness or loss of the former sense. The vision was $\frac{6}{12}$ and the intellect was clear. He died on April 22nd as a result of cancer of the pylorus. The brain was removed and placed in formalin. The right occipital lobe was considerably reduced in size; there was a distinct atrophic lesion in the posterior part of the fourth temporal convolution on the right side. On the left side there appeared to the naked eye no lesion whatever. However, on making a section of the left lobe there was found another atrophic lesion deeper down in the corresponding convolution. The optic nerves were found to be quite healthy. The lesion did not extend to the calcarine fissure. On microscopical examination the adventitia of the vessel was

Digitized by Google

considerably increased in amount, especially in the small vessels; in some of the small arterioles it was markedly increased. In some of the very small arterioles the media had become separated from the adventitia by a clear fluid. The microscopic preparations were made by Dr. Robertson, Pathologist to Morningside Asylum.

The PRESIDENT remarked that they were very much indebted to Dr. George Mackay and Dr. Dunlop for their interesting paper, as the subject was of great interest and a considerable amount of diversity of opinion existed with regard to the localisation of the colour centre in the brain.

Mr. GEORGE BERRY pointed out that although there was defect of the colour sense, the lesion did not limit the colour centre to that particular spot.

The PRESIDENT stated that he was of opinion that there were two distinct centres in the brain, one for colour sensation and another for the form sense.

Dr. GEORGE MACKAY, in reply, remarked that in cases of congenital colour-blindness the form was intact, which pointed to the presence of two distinct centres.

X Rays in Ophthalmology.

Mr. MACKENZIE DAVIDSON gave a demonstration of x rays and ophthalmology. He has applied the x rays to foreign bodies in the eye in 41 cases. The principle of the method is based on getting the three coördinates of any point. The instrument consists of a headpiece with a frame fitted with two knitting needles at right angles to one another, these form two planes and the sensitive plate forms the third plane. The head is then firmly fixed and the eye is directed to a point parallel to the horizontal knitting needle. The tube is placed exactly opposite the vertical needle and then a photograph is taken in that position. The tube is then moved 6 centimetres to one side or another, and then another photograph is taken in this position. By using these two films a stereoscopic effect is produced. The negatives are taken and developed and a piece of celluloid is placed over the wet plate and the position of the foreign body noted. The same is done with the second negative, the difference between these two points being recorded. The known point is located by an ingenious arrangement of silk threads and compasses, and by this means the exact position of the foreign body is estimated. To get accurate results by this method it is necessary to use tubes which form x rays which come from a very fine point, and also which require short exposures, about 90 seconds being the usual time required. Several lantern slides were exhibited illustrating many cases which he had had under his observation.

Mr. E. TREACHER COLLINS presented several cases in which skiagraphy was effective for detection of foreign bodies. The first case, that of a man four months after injury, showed a dark spot on the iris, and Mr. Davidson, by means of the x rays, located a foreign body behind the scar. The foreign body was removed, and excellent vision resulted. The second case described was that in which a piece of steel had penetrated the vitreous, located by Mr. Davidson by means of the x rays. It was removed by Mr. Collins, with a good result. The third case was one of iritis, and there was considerable doubt whether there was a foreign body present or not. It was, however, detected by Mr. Davidson in the iris, it having been in the eye for 14 years without causing irritation. The fourth case was that of a very small particle of flint in the lens, the measurement of which was barely 1 mm. in diameter. In conclusion, Mr. Collins mentioned that the method accurately locates the foreign body, also the size of the body, and whether there is one or more.

THE ANNUAL MUSEUM.

The Drill Hall in Forrest-road, the entrance to which is almost immediately opposite the reception room, afforded ample space for the display of new drugs, instruments, surgical and sanitary appliances, and other things of interest to the profession which annually form the nucleus of the museum. The exhibitors must have been encouraged by the very great interest which the visitors evidently took in the proceedings. From the point of view of merit the exhibits compared favourably with previous events: very good taste had been exercised in the arrangement of the stalls and the stalls themselves presented a very pleasing appearance. Pharmacy affords a wealth of material for the purposes of display, while the line of exhibits was now and then agreeably relieved by the products of other arts and industries, food preparations, mineral waters, scientific apparatus, illustrated periodicals, &c. The management very wisely had not overlooked the importance of allowing plenty of space between the rows of stalls so that the visitors could move freely up and down without uncomfortable jostling, and even when little groups collected round an object of particular interest there was no obstruction. This provision is a great help to those who are really bent on acquainting themselves with new things and modern improvements, not resting satisfied with a mere glance at the exhibits, but stopping awhile to discuss the merits or demerits, as the case may be, and perhaps exchanging ideas with brother practitioners.

In noticing the exhibits at that length which in point of merit they demand we may divide them as on previous occasions into seven sections—viz.: I., drugs; II., foods and food products; III., sanitary appliances, disinfectants, &c.; IV., surgical instruments and appliances; V., mineral waters, beverages, &c.; VI., publications; and VII., miscellaneous.

I. DRUGS.

In no other section of the annual museum is advance more striking and obvious than in that devoted to the exhibition of chemical and pharmaceutical products. More particularly will this appear so when the enormous progress which has been made in the forms of medicaments is considered. The pill is almost a thing of the past, having had to give way to the tablet, tabloid, palatinoid, and flexible capsule. And with these improvements in the design and administrative form of medicaments the drug which is thus presented has become a purer preparation, a more reliable and stable combination in the case of compounds, and satisfactory in regard to other points which are of undoubted importance in considering the therapeutics of the drug. Occupying a central position and illustrative of what we have just said was the admirably designed and electrically lighted stall of Messrs. Allen and Hanbury's (Plough-court, Lombard-street, London). Amongst the novelties of merit noticed were "Kapsols," or capsuled pills, consisting of various medicaments wrapped in a thin jujube coating. Side by side with these were the soluble capsules and "perles," tablets, throat pastilles, hypoderms, and the soluble gelatin coated pills. Then there were the tasteless oils, cod-liver oil and castor-oil, upon which this firm have bestowed considerable care and thought, and their labour has been rewarded in the attainment of "perfected" cod-liver oil and castor-oil, which are practically devoid of both unpleasant taste and smell. The series included also the valuable malt preparations, the basis of all of which is the well-known Bynin, a concentrated fluid extract. It forms an excellent vehicle for the ingredients of Easton's syrup, making a most pleasant tonic combination and withal is a digestive and nutrient. In the same way there are the "Perfected" Malt and Oil and Byno-hypophosphites, the latter a neutral solution of the hypophosphites of iron, calcium, potassium, and manganese and the alkaloids of cinchona and nux vomica. It is a perfectly stable combination, in which, too, the alkaloids are present in the condition in which they occur naturally. Considerable taste was displayed in the exhibit of Messrs. Oppenheimer, Son, and Co., Limited (Victoria House, Victoria Embankment, E.C.). The group was admirably arranged, the various palatinoids, placed in glass cups and jars of various shapes and sizes, tending not a little to the beauty of the whole design. The background consisted of soft plush in two colours which afforded a tasteful drapery. The applications of the palatinoid have apparently no limit. Thus there were palatinoids containing the extracts of animal substances, palatinoids of liquids, palatinoids of amyl nitrite, chlorodyne, chloroform and ether, beechwood creasote, &c. The value of the bipalatinoid appears emphasised in the compound syrups such as the syr. ferri hypophosph. co. and in ferrou carbonate with red marrow, a combination which has given excellent results in anæmia and chlorosis. The exhibit included the various digestive ferments and some new drugs—as, for example, hydrastin with cotarnin co. and cannabin tannate—used in gynæcological practice—and senecio aureus, a species of ragwort, a diuretic and emmenagogue. Messrs. Wyleys, Limited (Coventry), did not fail to place their fine pharmaceutical products to advantage and there were several novelties on view which were very prettily grouped. Mention should be made of the compound soluble liquors, as, for example, liq. aletris dulc., liq. viburni co., liq. papain et iridin, and liq. euonymin—all admirable

Digitized by Google

specimens of pharmaceutical skill. Pearl-coated pills, compressed pellets, "tropels" or compressed lozenges, flexible gelatin capsules, cachets, and pastels combined to make the array comprehensive and pleasing. Lastly should be mentioned "neuracetin," a comparatively new antipyretic and analgesic, drug which is said to be free from unpleasant after-effects; and "photopel," a handy developing photographic pellet. A new and interesting series of compounds was presented to view on the stall of the Pharmaceutisches Institut by Mr. Ludwig Wilhelm Gans, Frankfort-on-Maine. They are known as "halogenalbacids" and are said to be a means of administering the halogens, chlorine, iodine and bromine in an effectually therapeutic way without objectionable side effects. The iodalbacid contains 10 per cent. iodine and is reported to have yielded very encouraging results in syphilis and in other conditions in which iodine is indicated. Similarly, "bromalbacid" contains 6 per cent. bromine and gratifying results are recorded from its use in epilepsy. Lastly, "chloralbacid" contains 3 per cent. chlorine, the administration of this halogen albumen compound having been found useful in cases of chronic gastric catarrh and in dyspepsia. The feature of all these preparations is that they are albumen compounds which, while readily yielding the halogens indicated (chlorine, bromine, and iodine), are comparatively inert otherwise. We understand that at present there is no agency for the sale of these compounds in this country, but we were informed that samples would be forwarded gratis to medical men on application to Mr. Gans at the address indicated above. Examples of the application of pharmaceutical skill to the products of stable combinations were well shown at the neatly arranged stall of Messrs. Baiss Bros. and Company (Jewry-street, London). Foremost amongst these was Hopkinson's liq. colchicinæ salicyl, which has been prescribed with success in rheumatoid arthritis, chronic rheumatism, and gout. It is said to be without any depressing effect and a decided advance over colchicum wine and salicylic acid. To this should be added the mist. bismuthi. aromat., a palatable compound, pharmaceutically perfect, and of a composition of which the profession are informed. It is spoken of very highly in dyspepsia and gastric disturbance. The same preparation is combined also with pepsin as an important and valuable adjunct. Though, as might be expected, the stall of Messrs. Armour and Co. (59, Tooley-street, S.E.) was largely devoted to food products, of which we shall give an account later, yet there was an interesting and excellent collection of desiccated powders and tablets which properly come under the heading of this section. These were composed mostly of animal substances like cardin, cerebrinin, myelin, orchitic substance, ovarian tissue, pituitary body, red bone marrow, glycerine extract and powder, spleen, suprarenal capsules, thyroid gland, and so on. The experience of this well-known firm is a guarantee of the reliability and efficiency of these particular products. Messrs. C. J. Hewlett and Son (40 to 42, Charlotte-street, E.C.) brought to the notice of the visitor a very great variety of fine pharmaceutical preparations. We may mention in passing chione glabra, the decoction of the root of which in spirit yields a tincture of aphrodisiac properties, monsonia, which in the form of a rectified tincture has been employed as a remedy for dysentery with marked advantages over opium, and ipecacuanha preparations. Then there were also the animal organic substances and lastly the elegant pharmaceutical combinations of pepsine and bismuth, santal, buchu and cubebs now associated with the name of this firm. The excellent compound of cinchona, the hydrobromate, first successfully prepared by Messrs. Fletcher, Fletcher and Co. (Holloway, London, N.), was shown incorporated with vibrona champagne and "vibrona," the former being a pure *brut* wine containing a definite proportion of standardised cinchona bark in the form of neutral hydrobromate, and the latter a port wine each wineglassful of which corresponds to 5 gr. of red cinchona bark. We have already dealt critically with these preparations in Reports from THE LANCET Laboratory and also with the hydrobromate cachets which contain the neutral hydrobromate of cinchona. There was a very wide assortment of pharmaceutical preparations in the admirably equipped exhibit of Messrs Parke, Davis and Co. (21, North Audley-street, W.). Of particular merit were the standard fluid extracts standardised chemically, and where this is not possible physiologically, examples of which are afforded in ergot, cannabis Indica, digitalis and strophanthus. The exhibit contained also sugar-coated and gelatin-coated pills, enteric pills (passing the stomach but dissolving in the intestinal cavities), soluble gelatin capsules, tablet triturates, and digestive ferments, the most remarkable of which is taka-diastase possessing a remarkable amylolytic power under both an acid and alkaline environment. Messrs. H. C. Baildon and Son (73 and 144a, Princes-street, Edinburgh) offered some interesting novelties for inspection. In addition to the preparations for dermatological application which are associated with the name of Dr. Unna, the well-known Hamburg physician, there was exhibited a useful modification of iron pill known as pil. ferri co. (Dorall), the formula of which includes reduced iron, nux vomica, aloes, belladonna, and hyoscyamine. Worthy of attention also was the malt and mullein preparation which is a compound of pure active extract of malt and the juice of the mullein plant (Verbascum thaspus). This combination appears to promote nutrition and has been employed in wasting diseases. Finally, the exhibit included aperient fruit lozenges, the basis of which is the bark of the Rhamnus frangula. They act as a mild laxative and are free from drastic intestinal effects. Close by was an interesting collection, both historically and scientifically, of pharmaceutical preparations by Messrs. T. H. Smith and Co. (21, Duke-street, Edinburgh). The operations of this firm date, it appears, from the time when the late Sir James Simpson adopted chloroform as an anæsthetic, under whose guidance they paid special attention to the manufacture and purity of this product. In the exhibit were included some remarkably fine specimens of opium in lumps and sticks, while an exceedingly interesting series of the crystalline principles of opium, including codeine and other less known alkaloidal bodies such as xanthalin, were presented for inspection. Several specimens of the active principles of plants were also shown, as, for example, aloin, salicine, and piperine. Credit is due to Messrs. Robertson and Co. (35, George-street, Edinburgh) for the excellence of arrangement of their display. The preparation calling particularly for mention was the Blaud ferruginous pill, made in accordance with the original design and yielding pure ferrous carbonate as a product of inter-action of the ingredients. Besides this there was a praiseworthy series of gelatin capsules, discs, and "perles" and an antiseptic preparation in the form of dusting powder, or cream, as preferred, and known as "borozine," being a chemical combination of oxide of zinc and boric acid. Not far off was a series of synthetic remedies and other chemical and pharmaceutical preparations exhibited by Messrs. Raimes, Clark, and Co. (Edinburgh). On the same table was a series of specimens by the Scottish Acid and Alkali Company, Limited (Longford Chemical Works, Kilwinning, N.B.), relating to the preparation of iodine and iodides from "kelp" or seaweed ash. Amongst these was a beautiful collection of iodine crystals under a glass dome, the dome itself being filled with violet iodine vapour. Hydroxyl-free cod-liver oil is now well known to the medical profession, the elimination of the hydroxyl compounds securing a final product free from the tendency to cause nauseous eructations. This is the process of Mr. Peter Möller (43, Snow-hill, E.C.), whose stall was chiefly occupied by specimens of the oil thus refined, and illustrations were also given of the objections to the old process of preparation by which decomposition products were evolved. As might be expected the well-known firm of Messrs. Duncan, Flockhart, and Co. (104–106, South Canongate, Edinburgh) had a large and representative display of their special preparations. Foremost among these, not to mention the chloroform, the purity of which is deservedly and properly associated with the name of the firm, were the flexible yet non-collapsible gelatin capsules. Of these there were the following: Blaud's pill, Easton's syrup, cascara with or without euonymin, podophyllin, belladonna, nux vomica, &c.; potassium bichromate capsules and syrup of iodide of iron. In addition to these were perles, plastic pills, concentrated mixtures for dispensing, fluid extracts, and other elegant pharmaceutical preparations and combinations. It is enough to mention that the exhibit of chief interest under this section on the stall of Price's Patent Candle Co. was glycerine, which stands pre-eminently as an eminently pure product. This firm, we believe, were the first to separate and concentrate glycerine after the fatty acids of fats had been removed by saponification. We shall return to the rest of the exhibits of this firm, which properly come under the heading of another section. Messrs. Stephen

Digitized by Google

Smith and Co. (Malmesbury-road, Bow) decorated their stall chiefly with coca wine, which has already been reported upon in our analytical columns. The preparation is a standard one containing a definite proportion of the principles (intact) of the leaf of erythroxylon coca in combination with a sound port wine. In addition also was a beef wine known as "keystone" with the same wine as basis, but embodying the extractives of beef. The Maltine preparations (the Maltine Manufacturing Company, Limited, 24 and 25, Hart-street, Bloomsbury) have of late years been valuably extended, as, for example, in the combination of Maltine with coca wine, maltine with Easton's syrup, with pepsin and pancreatine, cascara sagrada, phosphates (chemical food), pyrophosphate of iron, &c. The value of such combinations with a reliably active malt essence will be readily conceded. Kutnow's effervescent Carlsbad powder has by the evidence of experience established its claim to being "improved." The active salts present are identical with the world-renowned Carlsbad salts except that they are desiccated, which offers distinct advantages for administration. Recent trials have also shown that the powder is valuable in constipation in infants, a quarter of a teaspoonful taken in milk or liquid food producing a mild, gentle action. In this exhibit also was submitted for inspection the pulvis Kutnovii anti-asthmaticus. There were three new interesting products on the stall of Messrs. Zimmer and Co. (33, Lime-street, E.C.). The first was "euquinine," a substitute for quinine in which a hydrogen atom has been replaced by a molecule of ethyl carbonate. It is said to present the therapeutic advantages of quinine without, however, its drawbacks. The second novelty was "eunatrol," a pure oleate of sodium, and why, therefore, coin a new name? Surely "pure oleate of sodium" is sufficiently descriptive and comprehensive. It is suggested as a cholagogue, having a favourable action on the secretion of bile. Lastly, "validol" is a combination of menthol and valerianic acid, the former being stated to be indefinitely soluble in the latter. It is described as "an excellent anti-hysteric, stomachic, and carminative," while recent experience would seem to point out the compound as worthy of further trial in seasickness. The exhibit of Messrs. Scott and Bowne, Limited (95, 96, 97, and 98, Great Saffron-hill, E.C.), was devoted entirely to "Scott's Emulsion," on which we have so recently reported in our analytical columns as to require no further comment. The "father" of malt extracts, that of Leopold Hoff (29, New Bridge-street, London, and Hamburg), was well represented, and an addition of some importance consists in a combination of the extract with manganite of iron. Mr. B. Kühn (36, St. Mary-at-hill, London) brought to the notice of the visitors to the museum the various preparations of value in surgical practice containing chinosol as a basis. Used in proper proportions this powerful antiseptic is non-poisonous, non corrosive, and soluble in water. In addition there were shown "iodoformogen" powder, a chemical compound of iodoform albumin with little smell but presenting the same properties of iodoform; tannalbin, a non-toxic intestinal astringent and useful in checking diarrhœa; diuretin, as its name implies a diuretic of value in many cases; colchi-sal, a solution of pure colchicine in natural methyl salicylate and betul-ol liniment for outward application where colchi-sal capsules are not tolerated by the stomach.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In July the following candidates passed in the subjects indicated:—

Surgery.—F. Adams, St. Thomas's Hospital; L. D. B. Cogan, Guy's Hospital; A. W. H. Edgelow, Charing-cross Hospital; J. L. Elliott and T. A. E. Fawcett (Section I.), Leeds; F. Hasler (Section II.), London Hospital; G. C. Hobbs (Section II.), St. Bartholomew's Hospital; A. J. Kennedy, Edinburgh; R. A. Lewty, Leeds and St. Mary's Hospital; E. P. Marett, St. Thomas's Hospital; L. R. Marshall, St. Mary's Hospital; M. Pantin (Section II.), Royal Free Hospital; E. J. Parry, St. George's Hospital; W. J. Schuller (Section I.), London Hospital; D. C. M. Shaw, Manchester; and A. P. Square, Middlesex Hospital.

Medicine.—F. Atthill (Section I.) and E. U. Bartholomew, Charing-cross Hospital; M. E. Bennett (Section II.), Royal Free Hospital; G. F. M. Clarke and H. E. Dalby, Charing-cross Hospital; A. G. C. Davies (Section I.), Guy's Hospital; S. E. Dunkin and J. M. Edwards (Section II.), Charing-cross Hospital; P. T. Goodman, St. Thomas's Hospital; E. J. Gruchy and F. Hasler (Section II.), London Hospital; E. S. Johnson, St. Mary's Hospital; A. J. Kennedy, Edinburgh; W. R. Wilson, Dublin and Belfast; and C. C. Worts, Guy's Hospital.

Forensic Medicine.—F. Atthill, E. U. Bartholomew, and H. E. Dalby, Charing-cross Hospital; A. G. C. Davies, Guy's Hospital; S. E. Dunkin, Charing-cross Hospital; E. J. Gruchy, London Hospital; J. W. Haigh, Leeds; A. J. Kennedy, Edinburgh; J. M. Sanderson, Cambridge and London Hospital; S. Sugden, Manchester; and C. C. Worts, Guy's Hospital.

Midwifery.—W. F. E. Ashton, Birmingham; E. U. Bartholomew, Charing-cross Hospital; M. E. Bennett, Royal Free Hospital; T. A. E. Fawcett, Leeds; P. T. Goodman, St. Thomas's Hospital; J. W. Haigh, Leeds; H. L. Hands, Charing-cross Hospital; F. Hasler, London Hospital; D. F. Kennard, St. Mary's Hospital; A. J. Kennedy, Edinburgh; E. P. Marett and W. P. R. Newth, St. Thomas's Hospital; S. Sugden, Manchester; J. Taplin, Birmingham; L. L. G. Thorpe, University College Hospital; and T. J. Vick, Guy's Hospital.

Messrs. F. Adams, J. L. Elliott, A. W. H. Edgelow, F. Hasler, A. J. Kennedy, R. A. Lewty, E. J. Parry, J. M. Sanderson, A. P. Square, and Miss M. Pantin were granted the diploma of the Society entitling them to practise medicine, surgery, and midwifery.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Degree of Doctor of Medicine (M.D.).—George Allen, M.B., C.M., Fife-Keith, Banffshire; Henry Angus, M.B., C.M., Bingley, Yorks; Wm. Henry Hewlett, M.B., C.M., Wivenhoe, near Colchester, Essex; Francis Kelly, M.B., C.M., Aberdeen; Frederick Marrant Robertson, M.B., C.M., London (old regulations); * David Ross, M.B., C.M., London; Alfred Tennyson Smith, M.B., C.M., Orpington, Kent; Daniel Malcolm Smith, M.B., C.M., Liscard, Cheshire; Robert Turner, M.A., M.B., C.M., Eastwood, Notts; and James Shirran Walker, M.B., C.M., Newton Heath, Manchester.

* Considered worthy of highest honours.

Degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.) (Old Ordinances).—Robert John Brown, Aberdeen; John Gerald Chalmers, Aberdeen; Alfred James Hynd, Aberdeen; John Gordon Smith Macpherson, Aberdeen; Ian Macquarrie, Conon Bridge, Ross-shire; Hector Munro, Fortrose, Ross-shire; Harry Michael Nicholls, Paglesham, Essex; and Charles Gabriel Peries, Colombo, Ceylon.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) (New Ordinances).—David Hunter Ainslie, Taitswell, Mintlaw, Aberdeenshire; Robert John Cheves, Middleton of Rora, Longside, Aberdeenshire; Robert Henderson Clarke, East Cottingwood, Morpeth; Frederick William Ellis, Hayle, Cornwall; Adam George Gordon Macleod Fraser, Aberdeen; David Albert Hutcheson, Aberdeen; Robert Fergus Hutchison, Ingleside, Cults, Aberdeen; Forbes Kinnear, Dysart, Montrose; Henry James McGrigor, Torry, Aberdeen; Donald Munro Maciver, Stornoway, Lewis; Farquhar McLennan, Achnashellach, Ross-shire; † John James Rickard Macleod, Aberdeen; Alexander Dalrymple McQueen, Aberdeen; George Jamieson Pirie, Rousay, Orkney; Charles Edward Preston, B.A., Wigton, near Carlisle; William Tuach, Redcastle by Inverness; and Alexander Brown Walker, Aberdeen.

† With honourable distinction. Awarded the Alexander Anderson Scholarship; *proxime accessit*, George F. Petrie.

The John Murray Medal and Scholarship (awarded to the most distinguished graduate (M.B.) of 1898) has been gained by Joseph Alex. Thomson, M.B., Ch.B., B.Sc. Cullen.

Diploma in Public Health.—Middleton Connon, M.B. (Aberd.), Aberdeen; Thomas Wright Parkinson. M.B. (Edin.), Brechin; and George Albert Turner, M.B. (Aberd.), Aberdeen.

MEDICAL MAGISTRATE.—Mr. Kenneth M. Chisholm, M.D. St. And., L.R.C.P., L.R.C.S. Edin., of Radcliffe, has been appointed a Justice of the Peace for the County Palatine of Lancaster.

WEST OF ENGLAND EYE INFIRMARY.—At the meeting of the governors of the West of England Eye Infirmary, Exeter, held on July 15th, it was stated that the donations and promises to the building fund now amounted to £6600. The building committee, seeing the urgent need for increased accommodation, recommended that the first section of the new works, which it is estimated will cost £30,000, should be commenced in August, but after considerable discussion it was decided not to commence building until £10,000 had been raised.

MANCHESTER ROYAL INFIRMARY.—At a meeting of the governors of this institution on Monday last, the chairman, Mr. E. S. Heywood, announced that Mr. Arthur H. Haywood, of Windermere, had presented to the infirmary a very interesting picture, a copy by a skilful artist of Sir Joshua Reynolds's portrait of the great surgeon, John Hunter, which hangs in the board-room of the Royal College of Surgeons of England. The copy is a most faithful and excellent representation, and will find a suitable home in the infirmary.

PRESENTATIONS TO MEDICAL MEN.—The members of the Clayton Branch of the St. John Ambulance Association on bringing their first and successful session to a close on June 23rd presented their instructor, Mr. E. G. Peck, L.R.C.P. Edin., M.R.C.S. Eng., of Queensbury, Bradford, with a fish knife and fork with pearl handles.—On June 27th Mr. G. S. R. Stritch, L.R.C.P., L.R.C.S. Edin.,

Digitized by Google

L.F.P.S. Glasg., of Spennymoor, was the recipient of a case of dental instruments and a gold signet ring from his patients and friends on the occasion of his leaving that town.—In connexion with the Bridlington Branch of the North-Eastern Railway centre of the St. John Ambulance Association, on awarding, on July 1st, efficiency certificates to the successful candidates, Mr. Theodosius Thompson, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Bridlington Quay, the honorary instructor of the class, was the recipient of a silver-mounted walking stick in grateful recognition of his ambulance instructions.—The members of the Society of Medical Phonographers have presented to Dr. Gray of Oxford, the first treasurer of the society, a gold fountain pen. Dr. Gray recently resigned the treasurership of the society.—Fifty-two years having elapsed since Mr. John Burns, F.F.P.S. Glasg., of Bridgeton, commenced practice there his many friends and patients recently expressed the desire to present him with some tangible token of their esteem. A committee was accordingly formed and subscriptions were freely offered by all classes of the community. After some consideration it was decided that the form of presentation should consist of a brougham for his use and a portrait in oils for the adornment of his home, and on July 5th, at the Albert Hall, Bridgeton, Mr. Burns was presented with a brougham, a set of harness, and an outfit for the coachman. The portrait will not be completed for a month or two, but when finished the committee intend to invite all the subscribers to witness the presentation.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Pharmacy Acts Amendment Bill.

THIS Bill has been passed without a provision to meet the case of companies carrying on the business of drug stores. The Lord Chancellor drew up such a provision, but at the last moment he determined not to move it. In announcing this decision his lordship said he quite recognised the need for legislation to meet the point, but he found that a great deal of machinery would be necessary and he did not see his way to encumber this Bill with it.

The Vaccination Bill.

The Vaccination Bill now stands for third reading in the House of Commons and against that motion there appears in the notice paper the following amendment by Mr. Duncombe—viz.: "That this House declines to proceed further with a Bill which, while removing all reasonable objections to compulsory vaccination, deprives the people of the United Kingdom of the proved advantages of the enforcement of the Vaccination Acts, 1867 and 1871."

HOUSE OF COMMONS.

THURSDAY, JULY 21ST.

Factory Prosecutions.

Mr. DRAGE asked the Home Secretary whether any cases had been brought to his notice in which women or children had been dismissed by their employers in consequence of evidence given by them in support of prosecutions undertaken by Her Majesty's Inspectors of Factories, and, if so, whether he proposed taking any action in the matter.—Sir M. WHITE RIDLEY replied: Yes, cases of this kind do from time to time come to my notice. As the law stands, however, I have no power to take any action in the matter, and in view of the great difficulties in regard to proof which are experienced in cases of a similar kind under the Witnesses' Protection Act, 1892, it seems very doubtful whether the matter can be remedied by legislation. Much more good, I think, can be done by the voluntary action of such a committee as I am glad to see is in process of formation for the very purpose of rendering help in these cases.

Diseased Foreign Meat.

Mr. BROADHURST asked the President of the Board of Agriculture whether he could inform the House of the number of cattle lost by death from disease in recent cargoes from the River Plate; whether he could inform the House of the nature of the disease; and whether in the case of those arriving in the Thames alive and slaughtered at Deptford a careful examination was made of the carcass to prevent suspected meat finding its way to the markets.—Mr. WALTER LONG replied: I have made inquiries on this subject but I find no reason to believe that any losses occur amongst cattle brought from the River Plate by reason of disease. The examination of the carcasses with a view to the protection of the public health rests with the local authorities, who in the particular instance referred to have appointed a special inspector for the purpose, but in addition the Board's veterinary officers are instructed to call attention to any carcasses which in their opinion are unfit for human food.

Tuberculosis.

Mr. BROADHURST asked the President of the Board of Agriculture whether he had reason to believe that tuberculosis was prevalent in the dairy herds of the country; and, if so, whether any steps were being taken to warn the consumers of milk of the danger to young children by drinking milk from cows so affected.—Mr. WALTER LONG replied: With regard to the prevalence of tuberculosis among dairy stock I would refer the hon. Member to the very full statement on the subject contained in the report of the recent Royal Commission. I do not myself think that the issue of any warning on the subject is necessary, but the matter is one for the consideration of the Local Government Board rather than of myself.—In reply to further questions on the same subject Mr. LONG said it was not at present contemplated to take any action on the recommendations of the Royal Commission, and as to circulating as a leaflet the information in the report on this subject that was a suggestion he should be quite willing to consider.

Dysentery in Upper Egypt.

Mr. LECKY asked the Under Secretary of State for Foreign Affairs whether the Government in Egypt had made any inquiry into the causes of the epidemic of dysentery which broke out at Assouan last February and led to the deaths of three ladies, and, if so, whether the report could be obtained; and what authority in Egypt inspected and was responsible for the sanitary conditions under which hotels and post-boats in Upper Egypt were conducted.—Mr. CURZON said that no information had been received at the Foreign Office as to cases of dysentery at Assouan last February, but Mr. Rodd would be asked to obtain a copy of any report which might exist on the subject and also in regard to the inspection of hotels and post-boats.

The Cantonment Rules.

Mr. JAMES STUART asked the Secretary of State for India whether in the draft cantonment rules sanctioned by him in his despatch of July 8th, 1897, it was provided that any medical practitioner who in the course of his practice becomes cognisant of the existence in any person of any infectious or contagious disorder shall be bound under penalty to give information to the cantonment authority, and whether the Indian Government had given any reason for omitting this provision in the cantonment regulations issued by them under date Oct. 15th, 1897, and now in operation.—Lord GEORGE HAMILTON said, in reply, the Government of India were of opinion that the rule to which this question refers was as originally drafted too wide and that it required modification. As, however, it was desirable to issue the rules without delay they decided to publish them without this particular rule which they reserved for further consideration, but it was, and is, their intention to restore it in a modified form. This will shortly be done and I will then lay it on the table of the House.

FRIDAY, JULY 22ND.

Treatment of Infectious Disease in the Navy.

Mr. MENDL asked the First Lord of the Admiralty whether the Admiralty intend to build an infectious diseases hospital on the eastern portion of the Naval Hospital grounds at East Stonehouse; and whether, having regard to the fact that this site is adjacent to a very densely and poorly populated quarter of the borough of Plymouth, the Admiralty would in any decision that may be arrived at in the matter consider the danger to the neighbourhood involved in the erection of a hospital for the treatment of infectious diseases; and whether the Admiralty were prepared to consider the advisability of maintaining hulks in Plymouth Sound for the purpose of isolating and treating infectious diseases such as are now maintained by the local authorities of Plymouth, Devonport, and Stonehouse.—Mr. AUSTEN CHAMBERLAIN, who replied for the First Lord, said: New wards for the treatment of infectious cases are being erected on the site named to replace the existing infectious wards, which are unsuitable for the purpose and are required for other cases owing to the growth of the fleet. The new wards will be properly isolated in accordance with the rules of the Local Government Board and will cause no danger to the surrounding district.

Experiments on Living Animals.

Mr. MACNEILL asked the Home Secretary whether his attention had been directed to the greater frequency of the admitted breaches of the law by vivisectors; whether any prosecutions had been instituted under the provisions of the Act of 1876 and if so how many; whether any convictions, and if so how many, had been obtained; whether his attention had been directed to the circumstance that in the return of experiments performed on living animals during the year 1897 Dr. Poore, the inspector, states on page 6 that illegal experiments performed admittedly by persons without the necessary licences and certificates have been recorded as performed by persons holding those licences and certificates; whether Dr. Poore had been asked to give any explanation of this inclusion of illegal experiments in the catalogue of legal experiments; how many inspections of places licensed for the practice of vivisection had been during the year 1897 severally reported to the Home Secretary by Dr. Poore and Sir James Russell; were these inspections carried on during the performance of experiments or were the bodies of the vivisected animals subsequently inspected; were there any inspections of experiments by operators with certificates enabling them to vivisect in unregistered places; and how are such inspections, if any, carried out; and whether he would publish the names of the persons who, on the admission of the report, have performed with impunity illegal experiments on the bodies of living animals.—Sir M. WHITE RIDLEY replied: There were two such cases in each of the years 1894-96 and seven in 1897, but all arose from inadvertence and were not, in my opinion, of a serious character and certainly were not fitting cases for prosecution. There has been only one prosecution under the Act and in that case the proceedings were dismissed. It is the case that two of the licensees (by what I am satisfied was mere inadvertence) omitted to apply for renewal of their licences. This is stated on page 5 of the report. It is also stated on page 7 that the list of licensees contains the names of these two gentlemen. The licences would certainly have been renewed if the ordinary application had been made. I see no objection to this course having been adopted. Dr. Poore paid 61 visits of inspection to licensed places in 1897 and Sir James Russell 68. Some of these visits took place during the performance of experiments and many animals that had been experimented upon were seen by the inspector. The only experiments performed elsewhere than at registered places are inoculation operations in connexion with the diseases of cattle and inspection in such cases is deemed unnecessary and does not take place. With regard to the publication of the names of persons who have performed illegal experiments, I do not think it necessary or right that such publication should take place when the illegality has not been of so serious a nature as to call for the institution of legal proceedings.

Food Products Adulteration.

Mr. CHAPLIN introduced a Bill "to make better provision against the adulteration of certain articles of agricultural and horticultural produce." The right hon. gentleman explained that the measure was

Digitized by Google

not introduced on grounds of public health, nor did it deal with any question of public health, because against adulteration which was injurious to health they believed the powers possessed under existing legislation were adequate. The object of the measure was to make the law more effective to prevent fraudulent trading in certain articles by adulteration or otherwise than it was at present under the Merchandise Marks Acts and the Sale of Food and Drugs Acts. The Bill dealt with food products only and did not refer to the other articles mentioned in these Acts which must be dealt with in another measure. In the case of foreign products the Commissioners of Customs were to take samples of consignments of imported milk or butter in accordance with directions given by the Treasury after consultation with the Board of Agriculture. A sample having been taken part of it was sent to the importer and part to the principal chemist of the laboratory at Somerset House, and it would be the duty of the latter to ascertain by examination whether the milk or butter was adulterated or impoverished within the meaning of the Bill—in other words, whether anything had been extracted from it or any foreign substance added to it so as to affect injuriously its substance, quality, or nature. If the sample proved to be adulterated the head of the laboratory was to inform the Commissioners and the Board of Agriculture of that fact at once. The Commissioners would then inform the importer, the Board of Agriculture would publish the fact, future consignments from the same quarter would be suspect, and the Commissioners of Customs would be empowered to detain any subsequent consignment bearing the same import marks and coming from the same suspected quarter, as if they were prohibited goods, unless the importer should have given the Commissioners security against the adulteration of the consignment. With regard to adulteration at home, the allegation was that, while the existing Acts would be perfectly adequate if they were efficiently administered, in some districts and in many cases they were to a large extent inoperative because the local authorities would not do their duty in enforcing them. It was proposed by this Bill to give to the Board of Agriculture power to direct any of its officers to procure samples of food which was exposed for sale or in course of delivery for sale; and if the Board was satisfied that it was adulterated within the meaning of the Act, then it would notify the fact to the local authorities of the place where the sample was taken and call upon them to be more active in the performance of their duty. If the local authority responded to the appeal nothing further would be necessary. If, on the other hand, they continued to be negligent the Board of Agriculture would have power to enforce the Act itself and to recover the costs from the local authority. In connexion with the taking of samples he reminded the House that the committee which sat upstairs on this subject recommended that there should be a court of reference to prescribe standards of quality and purity for all kinds and descriptions of food. Instead of setting up that rather cumbrous machinery the Bill provided that the Board of Agriculture, after causing such inquiry to be made as it might think fit, was to have the power of making regulations for determining what should or should not be considered adulteration or impoverishment in milk or butter within the meaning of the Act. Difficulties had not uncommonly arisen in the past owing to differences of opinion between the local analysts and the officers of the Government laboratory, and these difficulties would be obviated in the future by this proposal. Margarine which was imported as butter, or which was not distinctly marked and consigned as margarine in accordance with the law, would be liable to detention and would be dealt with under the provisions in Section 2 of the Bill to which he had referred. The mode in which margarine was to be marked was prescribed and the occupier of a manufactory of margarine or a wholesale dealer in margarine would be required to keep a register showing the quantity and destination of each consignment of margarine sent from his place of business, and this register was to be open to the inspection of an officer of the Board of Agriculture.—The right hon. gentleman had not completed his exposition of the Bill when he was called to order by the SPEAKER, who reminded him that under the rules of the House he was only permitted on this occasion to make a brief explanatory statement. Mr. Chaplin accordingly resumed his seat.

MONDAY, JULY 25TH.

Vaccination Questions.

Mr. LABOUCHERE asked the President of the Local Government Board whether public vaccinators as such were entitled to superannuation on pension terms under the present law, and, if not, whether they would be entitled to it if the Vaccination Bill became law; what was the number of public vaccinators in England and Wales, and in the event of their becoming entitled to a superannuation allowance under the Vaccination Bill would their previous service be taken into consideration in fixing the amount; how was it intended that the public vaccinators should be remunerated, whether by fee per visit, or by salary, or by each vaccination, and would such remuneration be payable by the local authorities, and if so what powers would they have to fix and alter the remuneration; whether the obligation to satisfy two magistrates of conscientious objection to vaccination, as set forth in the Bill, meant that this obligation must be undertaken by the father or that it might be fulfilled either by father or mother; and whether, if by the father alone, a child whose father was absent from his home during the period allowed for this formality could be contracted out of the obligation to be vaccinated by the mother appearing before two magistrates and stating her conscientious objection.—Mr. CHAPLIN said: The reply to the first paragraph is in the negative. The number of public vaccinators in England and Wales is about 3000. With respect to the third paragraph no matured decision has been at present arrived at, nor is it necessary, for the Act is not drawn to come into operation until Jan. 1st next. What is contemplated, however, is some arrangement like this: remuneration by two methods—first, by a payment based on the number of births to cover the general duties, and, secondly, by a payment in each case of successful vaccination; the amount of these payments to be a matter for arrangement in the first instance between the public vaccinator and the guardians by whom the payments will be made, subject, as in the case of all the principal officers of boards of guardians, to the approval of the Local Government Board. In answer to the last two paragraphs the obligation should be undertaken by the person in custody of the child, whether father or mother. If the father is prevented by absence or other unavoidable cause, then the duty would naturally fall on the mother.—Sir CHARLES DILKE asked the Lord Advocate whether it was intended to propose legislation to extend to Scotland any part of the provisions of the Vaccination Bill.—The LORD ADVOCATE replied: The system in regard to vaccination carried out in Scotland has hitherto worked successfully and the Secretary for Scotland cannot at present come under any obligation to propose legislation on the subject.—Mr. T. P. O'CONNOR asked whether it was not the case that in Scotland the defaulters were only 3 per cent. of the whole.—The LORD ADVOCATE: I cannot speak as to that but there has been no practical difficulty in working the Acts in Scotland.

Mischievous Advertisements.

Mr. CHANNING asked the Home Secretary whether he had considered the facts disclosed in the recent trial of Dr. Collins, and in many previous trials of similar character, and the use made in the St. Neots case of a notorious advertisement; whether he was aware that an enormous number of advertisements inciting to criminal offences of this nature are regularly being inserted in the metropolitan and provincial press, and that a vast amount of social mischief and crime was alleged to arise from these advertisements; and whether he would introduce or support effective legislation to prevent the insertion in the press or other distribution of advertisements of this class, and strengthen the law in dealing with incitements to these offences.—Sir M. WHITE RIDLEY replied that he was fully aware of the character of these advertisements, but legislation on the subject, he was afraid, would be a matter of great difficulty and he was not prepared at present to give any undertaking to introduce it. He would, however, bear the subject in mind.—Mr. CHANNING said that in consequence of this answer he begged to give notice that on an early opportunity next session he would introduce a Bill on the subject himself.

TUESDAY, JULY 26TH.

The General Medical Council and Unqualified Assistants.

Mr. LOGAN asked the First Lord of the Treasury if he was aware that in December last the General Medical Council passed a resolution disapproving of the employment by medical men of unqualified assistants, in consequence of which a large number of such assistants, who had been trained for the medical profession, many of whom have families, are and will be deprived of the means of obtaining a livelihood; and if there were any means whereby he could intervene and provide that those now or recently so employed shall be permitted to continue their vocation.—Mr. BALFOUR: In answer to the hon. Member I have to say that the General Medical Council did, as I am informed, pass a resolution against the practice of employing unqualified assistants for certain purposes which may in some cases have the effect which the hon. Member apprehends, but the resolution is not to be applied so as to restrict the proper training of pupils or prevent the legitimate employment of certain unqualified assistants under the immediate supervision of registered medical practitioners. The Privy Council, which has no official knowledge of the matter, cannot interfere to protect the persons affected, but it is understood that every case brought to the notice of the General Medical Council will be dealt with on its merits.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAMS, H., L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Physician for the Wellington Hospital, New Zealand.

ANSON, G. E., M.D. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Surgeon for the Wellington Hospital, New Zealand.

BARNES, J. S., M.D., B.S. Camb., has been appointed a Resident Medical Officer and Public Vaccinator for the Urban, Suburban, and Rural Districts of Katanning, Western Australia.

BLAXLAND, W., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed a Public Vaccinator for South Australia.

CHAPPLE, W. A., M.B. Univ. N. Z., has been appointed an Honorary Physician for the Wellington Hospital, New Zealand.

CLAYTON, G., has been appointed Public Analyst for the Parish of Fulham, S.W.

COLLINS, W. E., M.B. Lond., M.R.C.S., has been appointed an Honorary Surgeon for the Wellington Hospital, New Zealand.

CONNELLY, A. W., M.B., Ch.B. Melb., has been appointed a Resident Surgeon for the Bendigo Hospital, Victoria, Australia.

CORRY, W., M.D., Ch.M. Irel., D.P.H. Camb., has been appointed a Public Vaccinator for the Phillip Island Shire, Victoria, Australia, vice R. Jones, resigned.

DENBY, W., M.B., C.M. Edin., has been appointed a Medical Officer for the Fourth Sanitary District of the Bradford (Yorks) Union.

DOWE, S. A., M.D. Univ. Penn., U.S.A., has been appointed a Government Officer for the district of Bobadah, New South Wales.

FARQUHARSON, W. F., M.B., C.M. Edin., has been appointed Medical Superintendent for Garlands Asylum, Carlisle, vice J. A. Campbell.

FYFFE, E. H., M.B., Ch.M. Glasg., has been appointed an Honorary Pathologist for the Wellington Hospital, New Zealand.

GARDNER, H. BELLAMY, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Anæsthetist to the Charing-cross Hospital, London, vice F. W. Hewitt, resigned.

GODFREY, C. G., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Acting Medical Superintendent for the Ballarat Lunatic Asylum.

GRANT, DAVID, M.D. Edin., Ch.M., has been appointed an Honorary Physician to the In-patients of St. Vincent's Hospital, Melbourne, Australia.

GWYNNE, C. N., M.D. M.Ch. Dubl., L.M.R.C.P. Irel., has been appointed a Certifying Surgeon under the Factories Act, Sheffield, vice R. J Pye-Smith, resigned.

Digitized by Google

HIGGINS, F. C., M.B. Syd., has been appointed a Government Medical Officer and Vaccinator at Walgett, New South Wales.

JAMES, D. P., F.R.C.S. Eng., L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Surgeon for the Wellington Hospital, New Zealand.

LESLIE, W. M., M.D., C.M. Edin., has been appointed to assist the City Judges as Medical Referee under the Workmen's Compensation Act, for cases arising in the City of London.

LIMRICK, W.S., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health by the Waterloo-with-Seaforth Urban District Council.

LLOYD, J. W., M.R.C.S., L.R.C.P. Lond., L.D.S. Edin., has been appointed an Honorary Surgeon for the Liverpool Dental Hospital.

MACFARLANE, WM., M.D., C.M. Glasg., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Sheriffdom of Ayr.

MACKAY, ALEX., M.D., C.M. Glasg., has been re-appointed a Medical Officer of Health by the Crook Urban District Council.

MACKENZIE, F. W., M.B., C.M. Edin., has been appointed an Honorary Ophthalmic Surgeon for the Wellington Hospital, New Zealand.

MARTIN, A., M.D. Lond., M.R.C.P., M.R.C.S., has been appointed an Honorary Surgeon for the Wellington Hospital, New Zealand.

MARTIN, FRED. W., M.R.C.S., L.R.C.P. Edin., has been re-appointed Medical Officer of Health for the Borough of Brighouse.

MCGEE, J. H., M.D., B.Ch. Irel., D.P.H. Camb., has been appointed an Honorary Physician to the Out-patients, St. Vincent's Hospital, Melbourne, Australia.

NEWMAN, F. A., M.B., Ch.B. Melb., has been appointed Honorary Physician to Out-patients, St. Vincent's Hospital, Melbourne, Australia.

POLLEN, H., M.D. Dubl., L.K.Q.C.P. Irel., has been appointed an Honorary Physician for the Wellington Hospital, New Zealand.

POWELL, HENRY WILLIAM FITZGERALD, M.D., F.R.C.S. Edin., has been appointed a Physician to the Hospital for Diseases of the Throat, Ear, and Nose, Golden-square, London, W.

PYE-SMITH, R. J., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Sheffield and Rotherham County Districts of Circuit No. 13.

ROSENFIELD, R. L., M.B. Melb., has been appointed a Government Medical Officer and Vaccinator for the district of White Cliffs, New South Wales.

RYAN, T. F., M.B. Melb., has been appointed, *pro tem.*, Acting Public Vaccinator at Nhill, Victoria, Australia.

SELLS, C. J., L.R.C.P. Lond., M.R.C.S., has been re-appointed a Medical Officer for the Worplesdon Sanitary District of the Guildford Union.

SHARMAN, MARY NONA, M.B. Lond., has been appointed House Surgeon for the Victoria Hospital for Sick Children, Hull.

SOMERSET, W. R., M.B., Ch.B. Edin., has been appointed an Assistant House Surgeon for the Worcester Infirmary.

SMITH, J. M., M.B., C.M. Edin., F.R.C.S. Eng., has been re-appointed Junior Anæsthetic Medical Officer for the Manchester Royal Infirmary.

STURDY, J. C., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the Fifth Sanitary District of the Bradford (Yorks) Union.

TEARE, J., M.B., B.S. Vict. Univ., Manchester, has been appointed an Honorary Physician for the Wellington Hospital, New Zealand.

THORNE THORNE, LESLIE, M.D. Durh., B.S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Examiner to the Technical Education Board of the London County Council.

WILSON, G. B., L.R.C.P., L.R.C.S. Edin., has been appointed a Public Vaccinator for South Australia.

WOODSIDE, R. N., M.B. Melb., has been appointed a Medical Superintendent for the Albury Hospital, New South Wales.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £50, with board and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Birmingham.—Honorary Medical Officer.

BOROUGH OF DERBY.—Medical Officer of Health. Salary £500 per annum, increasing by £50 per annum to £600 at intervals of two years. Applications to the Town Clerk, Town Hall, Derby.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE, Chelsea, S.W.—A Teacher of Hygiene.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

COUNTY ASYLUM, Gloucester.—Locum Tenens for about two months. Salary £2 2s. per week and all found (except liquors).

CROYDON RURAL DISTRICT COUNCIL.—Deputy Medical Officer of Health for one year. Salary at the rate of £550 per annum, which will include travelling and all other expenses. Applications to the Clerk, Town Hall, Croydon.

CUMBERLAND AND WESTMORELAND ASYLUM, Carlisle.—Senior Assistant Medical Officer. Salary £120 a year, with board. Applications to Dr. Farquharson, Garlands, Carlisle.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Assistant House Surgeon for twelve months. Salary £40, with board, residence, and washing.

DEVONSHIRE HOSPITAL, Buxton.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence in the Institution.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Resident Medical Officer for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

NORTHAMPTON GENERAL INFIRMARY.—Junior Assistant House Surgeon for six months. Board, lodging and washing provided and an honorarium of £10 will be given conditionally.

OWENS COLLEGE, Manchester.—A Senior and Junior Demonstrator in Physiology. Stipends £150, rising to £200, and £100, rising to £150, respectively.

ROYAL INFIRMARY, Sheffield.—Junior Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing.

RURAL DISTRICT COUNCIL OF CHESTERFIELD.—Medical Officer of Health for one year. Salary at the rate of £500 per annum, which includes all expenses, stationery excepted. Travelling expenses outside the district will be allowed. Applications to the Clerk to the Council, Union Offices, Chesterfield.

SALFORD SCHOOL BOARD.—Medical Officer. Salary £150 per annum. Applications to the Clerk to the Board, School Board Offices, Salford.

SOMERSET AND BATH ASYLUM, Wells, Somerset.—Junior Assistant Medical Officer, unmarried. Salary £110, rising to £130, with board, lodging, washing, and attendance.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeons for six months. Honorarium at the rate of £30 per annum and residence, board, and washing provided.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Assistant House Surgeon for six months. Board, washing, and lodging in the hospital provided.

THREE COUNTIES ASYLUM.—Second Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with board, apartments, washing, and attendance. Applications to the Clerk to the Committee of Visitors, St. Neot's, Hunts.

UNIVERSITY COLLEGE, Bristol, Faculty of Medicine.—Demonstratorship of Physiology. Stipend £125.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, Cardiff.—Assistant Lecturer and Demonstrator in Anatomy. Stipend £120 per annum. Also temporary Assistant Lecturer and Demonstrator in Physiology for one year. Salary £120. Applications to the Registrar, University College, Cardiff.

WEST DERBY UNION.—Resident Assistant Medical Officer for the Workhouse, Rice-lane, Walton-on-the-Hill, Liverpool. Salary £80 per annum, with first-class rations, apartments, &c. Applications to the Union Clerk, Brougham-terrace, West Derby-road, Liverpool.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Medical Officer to the Provident Dispensary attached to the hospital. Salary £80 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BRUCE.—On July 24th, at Goole, Yorks, the wife of R. C. Bruce, M.B. Edin., of a son.

GUBBIN.—On July 11th, at New Brompton, Chatham, the wife of Surgeon-Major G. F. Gubbin, Royal Army Medical Corps, of a son.

KEOGH.—On July 23rd, at Oxford-gardens, North Kensington, the wife of Frederick E. Keogh, L.S.A., of a son.

POWELL.—On July 21st, at Morning-lane, Hackney, the wife of Henry Christoffers Powell, L.S.A., of a son.

MARRIAGES.

BATTERSBY—AYRE.—On July 20th, at St. Nicholas Church, Withernsea, by the Rev. J. G. Patrick, Vicar of Owthorne, assisted by the Rev. C. Day, Vicar of Withernsea, and the Rev. F. Weston, Vicar of Balby, John Hargreaves Battersby, M.D., of Balby, Doncaster, second son of the late Richard Battersby, of Heywood, Lancashire, to Lily Rachael, elder daughter of H. H. Ayre, of Withernsea, East Yorkshire.

BOWIE—CHICHELE PLOWDEN.—On July 20th, at Christ Church, Lancaster-gate, Alex. Bowie, M.D., C.M. St. And., L.R.C.P. Edin., of Hertford-street, Mayfair, to Henrietta A., only daughter of the late Captain H. Chichele Plowden, Bengal Staff Corps.

CRAWFURD—BAILEY.—On July 22nd, at Harwood Parish Church, Bolton-le-Moors, Raymond Henry Payne Crawfurd, M.A., M.D. Oxon., M.R.C.P. Lond., of Wimpole-street, W., to Ethelberta Ormrod, youngest daughter of Arthur Bailey, Esq., of Brightmet-hill, Bolton-le-Moors.

DALBY—JEX.—On July 25th, at St. Paul's, Brighton, by the Rev. J. H. Ashley Gibson, M.A., John Lyttleton, of Norfolk House, 13, Buckingham-road, Brighton, only son of Major N. B. Dalby, of Ealing, to Mary, daughter of Mrs. B. Jex, of 44, First Avenue, Hove, late of British Honduras. No cards. At home Oct. 1st and 8th, 4 to 6.

MAHOOD—SCOTT.—On July 6th, at Northam Church, Allan Edward Mahood, M.B., F.R.C.S., of Odun House, Appledore, to Caroline Eva Stanley, eldest daughter of the late Lieut.-Col. Stanley Scott, Bombay Staff Corps, formerly of Northam House, Northam, North Devon.

MUIR—PERKS.—On July 21st, at St. James's Church, Kidbrook, Arthur Muir, M.B., B.C., of Enfield, to Francis Annie (Dolly), only daughter of John B. Perks, of Blackheath.

DEATHS.

GARLIKE.—On July 19th, at Malvern Cottage, Ealing Dean, Ealing, Thomas William Garlike, F.R.C.S., aged 82 years.

JOHNSTON.—On July 24th, at his residence, Edendariff, Cheltenham, Surgeon-General William Johnston, M.D., late Madras Army, aged 81 years.

MORRISSON.—On July 23rd, at Hollier's-hill, Bexhill, Sussex, Stammers Morrisson, L.R.C.P. Lond., M.R.C.S., late of Clapham-common, aged 56 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

"THE TREATMENT OF SEA-SICKNESS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 25th a correspondent about to sail as surgeon to a passenger steamer begs for advice as regards medicines for sea-sickness. Moreover, he states that the majority of the text-books are silent on the subject. During the last twenty years I have myself made about forty short voyages and have been often applied to by patients in search of a remedy for this distressing complaint. Also I have taken many opportunities of consulting ship surgeons as to the best treatment, but although they are always charming men and sometimes of great professional skill they are openly bored by the subject of sea-sickness. Prior to 1892 the drug which seemed to be most useful to sufferers was bromide of potassium or sodium with or without hydrobromic acid, but to produce a satisfactory effect the patient had to take doses sufficiently large to produce unpleasant mental effects. I have seen patients arriving in Cairo and remaining ill for several days from severe bromism. I believe that the patent remedies sold in England and America contain bromides as their chief ingredient. When, therefore, I read in THE LANCET of March 5th, 1892, Professor Charteris's praise of a mixture of bromide and chloralamid I at once felt that here was a combination which might act better than bromide alone. Since then this mixture, chlorobrom, has been often praised and seldom abused in the pages of THE LANCET—as, for example, in the issues of June 24th, 1893 (Dr. Ledingham), and Jan. 19th, 1895. I have tried it now on many patients and can on the whole praise it as the best known drug. I began by prescribing it to twelve people, each of whom had made many journeys and had invariably suffered from very severe sea-sickness, sometimes incapacitating them for a couple of days after landing. Some of these also suffered from train-sickness and some used as children to vomit when driven in carriages. This severe test answered on the whole fairly well and I bound each of the twelve over to write and tell me the result. Eight were surprised to find that they did not vomit, wrote grateful letters, and wanted to know if they might give it indiscriminately to all their friends. Two reported well, but said the sea was so smooth that the test was not a fair one; and two others wrote to say that it failed entirely though they had carried out all my instructions. I ought to say that most of my test cases were ladies between twenty-five and fifty-four years of age. Even in cases where the chlorobrom fails to prevent nausea and vomiting the patients are grateful for the sleep which it produces. One of my early cases, a young man with dangerous symptoms, took too much of the drug and wrote afterwards: "Although for the first 2½ days we were on board we had awfully rough weather I never experienced the faintest symptoms of sea-sickness, so that the medicine was entirely successful in that respect. On the other hand it reduced me to such a deplorable state of drowsiness and (as my friends said) apparent intoxication that at the end of 2½ days they induced me to give it up fearing that it was having too much effect on my head. Altogether I was most thankful for the medicine, &c." This, so far as I know, is the only bad result of the remedy. I began by prescribing wafers of bromide and chloralamid in equal parts, but a solution is obviously easier to take and to those abroad who cannot get the liquid chlorobrom sold in England I would point out that a very good imitation can be made by dissolving the chloralamid in rectified spirits. No drug can be guaranteed to prevent sea-sickness, and to give chlorobrom a fair chance aperients must be taken before and during the voyage, diet on board must be sparing and simple, a belt should be worn, and the first dose of chlorobrom must be taken the night before embarking.

I am, Sirs, yours faithfully,

Cairo. F. M. SANDWITH, M.D. Durh.

"INCARCERATION OF THE PENIS."

To the Editors of THE LANCET.

SIRS,—The case mentioned by you in THE LANCET of July 23rd under the care of Dr. Floras reminds me of a somewhat analogous case which came under my notice some years ago. A man consulted me with reference to his penis. The prepuce was retracted and the glans exposed, a condition which had existed for some years. He had tried every means he knew to return the prepuce to its original position over the glans without success, and as he said it had latterly caused him much irritation he wished to know if I could help him surgically. I, however, told him it was a matter of no great importance and that he had better put up with it. Some weeks afterwards he reappeared and said he had overcome the difficulty himself. On examination, I found his penis ornamented with a brass ring. He had drawn the prepuce well forward, and laying it on a block (probably the village butcher's) had transfixed it with a bradawl, afterwards inserting the brass ring; the wound in the prepuce had quite healed, and there the brass ring remained. He was a married man. I never saw him again.

I am, Sirs, your faithfully,

July 26th, 1898. J. G. B.

A MATTER OF TASTE.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me if it is the correct thing for a Fellow of a College of Surgeons when signing certificates, &c., to add the initials of his college as Eng., Irel., Edin., for it appears that the London men arrogate to themselves the right to sign F.R.C.S. without the addition of "Eng." There appears to be no rule or custom for medical graduates. Thanking you beforehand for an authoritive opinion,

I am, Sirs, yours faithfully,

July 25th, 1898. R. N.

*** It is better in our opinion that diplomates of the various colleges and graduates of the various universities should indicate the source of their distinctions, but to do so is quite optional. A F.R.C.S. Eng. omitting his "Eng." hardly stands convicted of arrogance.—ED. L.

A POINT UNDER THE EMPLOYERS' LIABILITY ACT.

To the Editors of THE LANCET.

SIRS,—An expression of opinion is desirable on the following points anent the operation of the new Employers' Liability Act—viz., power of entry of hospital by the employer's professional representative for the purposes of examination of the injured person, also a definition of the word "examination"—i.e., to what extent it may be permitted or restricted?

I am, Sirs, yours faithfully,

July 18th, 1898. A HOSPITAL SURGEON.

*** So far as the employer's surgeon is concerned there is no right of entry or right of examination either in hospital or in a private house. The examination contemplated by the Act is obviously such examination as is necessary to enable the employer's surgeon to form an opinion upon the questions at issue—e.g., the extent and degree of injury, probable time and degree of recovery, fitness for work of one or another kind, &c. It would be impossible to define all this, and the attempt to do so is unnecessary seeing that there is no obligation upon the patient to submit to it.—ED. L.

OVERLAYING.

To the Editors of THE LANCET.

SIRS,—The question of "overlaying" crops up again and again, and I would like to offer a suggestion which might be more acceptable than the substitution of an "orange-box for a cot." This expedient seldom finds favour in the eyes of the class to which it is so often advised, who always persist in sleeping with their infants. Briefly, a sort of hammock may be made by fastening the ends of a piece of material about 27 in. wide (a sheet folded lengthwise would do) to the centre of the bar at the head and foot of the bed respectively. The dependent part of this hammock should clear the level of the bed by some inches. No pillow is required, so that the additional danger of the child turning over on its face and being suffocated (which might occur in the most well-appointed cot) is avoided, as the single, or even double, fold of material would not prevent respiration. The supply of air would be less contaminated and there would be no danger of falling out of bed.

I am, Sirs, yours faithfully,

O. HALL, L.R.C.P., L.R.C.S. Edin., &c.

Holmside, co. Durham, July 23rd, 1898.

"UNFORTUNATE PUBLICITY."

WE have received a long letter from Dr. J. F. Bullar, in which the following passage occurs:—"Some time ago the inspector of schools for this district asked me to examine the eyesight of the children in the board schools. There are about 16,000, the work was to be unpaid and I thought it judicious to decline; but I explained how I thought the masters might make a preliminary examination that would be useful. I prepared certain forms with instructions for their use and further demonstrated to the masters the manner of using them. It became necessary to print the forms and the inspector of schools kindly undertook to get it done. In due course I received a copy of what you describe as the 'book.' I proposed to share the cost of printing with the inspector but he informed me that he had arranged with Messrs. Cox and Sharland to publish it free of cost, they to have any possible profit that might be made." We believe with difficulty that Dr. Bullar's work would be advertised in the publishers' penny time-table against his will, but Dr. Bullar says that he sees no objection to the advertisement. He says also that the proposition that there are patent objections to anything which advertises the writer in his medical character to a lay public is "bosh." We can give no more space to the matter.

"A QUESTION OF ETHICS."

To the Editors of THE LANCET.

SIRS,—Under the above heading the wording of Mr. Cuffe's recent circular is criticised in THE LANCET of July 16th. As the circular was addressed only to the members of our profession and calls attention to a grievance which I know to be common to many health resorts, as well as in London itself, I do not think Mr. Cuffe's action should be condemned. In giving patients letters of introduction addressed to specialists whose opinions I have been anxious to obtain I have often been annoyed to find that the hotel manager or lodging-house keeper has persuaded them to consult someone else. This has occurred frequently in London, in Brighton, Bath, and Harrogate. I now write direct to the specialist and merely give the address to the patient, telling him at the same time that I have described his case to the doctor whom I wish to consult. This, I think, is all Mr. Cuffe asks his medical friends to do.

I am, Sirs, yours faithfully,

July 25th, 1898. FAIRPLAY.

Perplexed.—We give an opinion on the case as disclosed by "Perplexed." It is not right of X or Y to expect A to work for Y without extra remuneration when he has only been engaged to work for X. The legal side turns on the interpretation of the terms of agreement between A and X, which we do not know, and on which a solicitor should be consulted before action is taken.

Indecipherable.—We shall be pleased to learn the name of a recent correspondent whose interesting letter is dated from the Royal Colonial Institute, but whose signature has baffled all our attempts to decipher it.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

WEDNESDAY (3rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (4th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex, (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (6th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

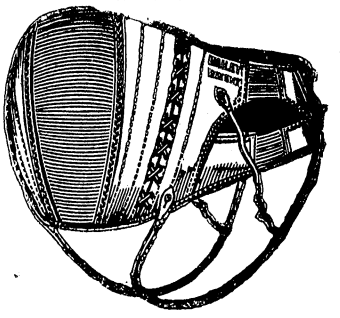
BAILEY'S PATENT ABDOMINAL BELTS.

For General Support, Pregnancy, Prolapsus Uteri, Umbilical Hernia, Uterine Support, Laparotomy, Floating Kidney.

FOR GENERAL SUPPORT.

Over 15,000 of these Belts have been sold. The only ones which will not ruck up.

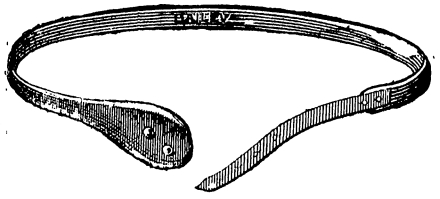


No Belt which is cut in one piece can give efficient support to the abdominal walls without undue pressure on the hips.

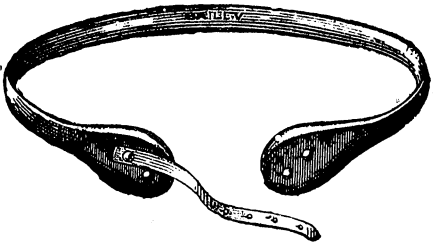
They are so constructed that the part which surrounds the abdomen is distinct from that which surrounds the hips, so that each part can be adjusted properly, and as the size of the hips varies very much in different persons, this is a matter of the first importance.

The Greatest Improvement ever Effected.

Attested by hundreds of unsolicited Testimonials from eminent Members of the Medical Profession and others.



FOR PREGNANCY.



SPECIAL DEPARTMENT FOR LADIES. 18/-, 25/-, 35/-, 45/-; *usual Discount.*

All Belts are made and fitted on the Premises. Or competent assistants sent to measure.

BAILEY'S WASHABLE TRUSSES.

"NO GOOD RESULTS CAN BE OBTAINED FROM ANY TRUSS WHILE THE DAILY BATH IS TAKEN WITHOUT ONE. TO EFFECT A CURE THE RUPTURE MUST NEVER BE ALLOWED TO COME DOWN."

THIS can be effected by wearing one of Bailey's Washable Trusses, which, as they do not absorb any moisture, require no drying. They can be worn also as an ordinary truss, so that for sea-bathing it is not necessary to carry a duplicate.

They are covered in a strong, flexible, and very durable enamel, which will last for years, and are therefore especially suitable for the bath, for travellers, for sea voyages, and the tropics. There is nothing to wear out as in the ordinary leather-covered trusses, and they are unaffected by moisture or perspiration.

Anticipating a large sale for these Trusses, we have fixed the prices as low as possible.

For measurement, send the circumference of the pelvis two inches below the crest of hip bone, and state right left, or double.

Single, each 10s. 6d. Double, each 15s.

BAILEY'S SPECIAL CLINICAL THERMOMETERS.

REDUCED  **PRICES.**

Guaranteed all English made. *Special Prices by the dozen. Postage 3d.*

"Does not depress the Heart."

ANTIKAMNIA (C_NH_{2N-6}).

OPPOSED . . . . . TO PAIN.

PROF. H—— E——, A.M., M.D.,

Fellow of the American Academy of Medicine, points out one or two important facts in regard to ANTIKAMNIA. He says:—

"Antikamnia possesses no merit as a preventive of pain; its action is *nil* until the pain begins.

"Antikamnia, when given in five-grain doses every ten minutes until grs. xxx. have been taken, produces no effect whatever in a *healthy* person. As my investigation concerned its action under pathological conditions, I did not inquire further into the question how much more than thirty grains might be administered to a healthy person without any deleterious effect.

"The action of Antikamnia as an analgesic begins the moment an individual is attacked by pain; and here a great number of observations has established with me the following rule for its administration to adults:—

"As early as possible after the pain has developed—if possible, immediately after—Antikamnia grs. v. are taken; from three to four minutes later, if the first dose has no, or but little, effect, the same dose is repeated; and again three or four minutes later, provided again the effect is *nil* or not sufficient, this dose is administered the third time. Then I let the patient wait ten minutes; if by the end of that time the pain be greatly ameliorated but a trace of it still present, a fourth dose of gr. v. then (i.e., ten minutes after the third) given will generally stop the pain completely."

Prof. E——'s observations have been confirmed and reinforced in England by eminent physicians. *See signed reports*, MEDICAL REPRINTS, *January, 1896 and November, 1896.*

EDINBURGH MEDICAL JOURNAL says:

"This is one of the many Coal-Tar products which have lately been introduced into medicine. . . . In doses of three to ten grains it appears to act as a speedy and effective antipyretic and analgesic."

The American antipyretic, anodyne, and analgesic, is a combination of Coal-Tar derivatives of the series CnH2n-6, into which the amines have entered, forming the various amido-compounds.

It has, in contradistinction to other coal-tar products, a stimulating action on the nerve centres and the vital functions, especially the cardiac system.

It occurs in microcrystalline powder, and is perfectly white in colour; of a slight pungently bitter taste and alkaline reaction. It is moderately soluble in water, more freely with glycerine sparingly added, and freely soluble in brandy, whisky, or wines, according to their alcoholic percentage. In liquid prescriptions, however, simple elixirs offer the best vehicles.

ANTIKAMNIA should not be dispensed, however, in any vehicle of acid reaction. It can be readily given in tablets, as well as in powder (dry on the tongue) followed by a swallow of water or wine.

DOSE for Adults—5 to 15 grains; for Children in proportion. As a pain reliever in Neuralgia, Rheumatism, &c., ANTIKAMNIA acts with safety, certainty, and celerity.

PRICE OF ANTIKAMNIA TO THE MEDICAL PROFESSION.—**In three-grain or five-grain Tablets, or in Powder, 3s. 9d. per Ounce. One-ounce packages only. Price to the public (on prescription only), 4s. 6d. per Ounce.**

ANTIKAMNIA COMBINATIONS.—**Antikamnia and Codeine Tablets** (4¼ gr. Antikamnia, ¼ g., Sulph. Codeine); **Antikamnia and Quinine Tablets** (2½ gr. Antikamnia, 2½ gr. Sulph. Quinine); **Antikamnia and Salol Tablets** (2½ gr. Antikamnia, 2 gr. Salol).

Thyroid.

To name the affections in which the Thyroid treatment has been tried would necessitate the enumeration of a long list of pathological conditions.

It is a specific of the first importance in Myxœdema, Cretinism, Goitre and Obesity. It is of great value in Acute and Chronic Melancholia and Acute Delirium. The results following its employment in Psoriasis, Scleroderma, Eczema, Tetany, and certain phases of Insanity, and in retarded development of children, have been such as to warrant further experiment.

Armour's Desiccated Thyroid
Thyroid Tablets
and Elixir Thyroid

are carefully made from selected material, and may be depended upon in all cases where the Thyroid treatment is indicated.

Bone Marrow

acts as a Stimulant to the Formative Processes and increases the production of red blood corpuscles and hæmoglobin, making it the ideal remedy in all diseases due to defective hæmogenesis.

The best results follow the use of a preparation made with Marrow taken from the animal immediately after it is killed.

Glycerine is practically the only medium for preserving the product in an unaltered condition.

Armour's Extract of Red Bone Marrow

Is made from absolutely fresh material and pure Glycerine, and contains all the essential ingredients of raw Marrow.

ARMOUR & COMPANY (Chicago), LONDON, S.E.

Will be pleased to send Samples of any of their Laboratory Products to Physicians interested, with Pamphlets.

That Medical Man is yet to be found who after investigation and trial fails to fully endorse the claims made for

FELS'S GERMICIDE SOAP.

Nearly three thousand letters of approval have been received from the Medical Profession of Great Britain, showing that in Obstetrics, most forms of Skin Diseases, in Dental Practice, as a Germicide, as a Deodorant, and in numerous other uses, including the Toilet,

FELS'S GERMICIDE SOAP

stands alone.

It contains HYDRARG. BICHLORID., SAL. ALEMBROTH, B. NAPHTHOL, and EUCALYPTOL.

Every Physician who tests it believes in it.

Every modern Chemist stocks it and sells it at protected prices.

All Wholesale Houses supply it.

1/- per CAKE; 8/4 per Dozen.

SYR. HYPOPHOS. CO. FELLOWS.

NOTICE—CAUTION.

The success of Fellows' Syrup of Hypophosphites has tempted certain persons to offer imitations of it for sale. Mr. Fellows, who has examined samples of several of these, FINDS THAT NO TWO OF THEM ARE IDENTICAL, and that all of them differ from the original in composition, in freedom from acid reaction, in susceptibility to the effects of oxygen when exposed to light or heat, IN THE PROPERTY OF RETAINING THE STRYCHNINE IN SOLUTION, and in the medicinal effect.

As these cheap and inefficient substitutes are frequently dispensed instead of the genuine preparation, physicians are earnestly requested, when prescribing the Syrup, to write "Syr. Hypophos. FELLOWS."

As a further precaution, it is advisable that the Syrup should be ordered in the original bottles (4s. or 7s.); the distinguishing marks which the bottles (and the wrappers surrounding them) bear, can be then examined, and the genuineness—or otherwise—of the contents thereby proved.

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic,** we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialties—

SOMATOSE

is an Albumose Food product. It is prepared from meat, and contains the albuminous elements of the latter in an easily soluble form. The salts present in SOMATOSE correspond to the nutritive salts of fresh meat, among which occur Phosphate of Potassium, so important in the formation of muscular and cellular tissue.

SOMATOSE is a Tasteless, Odourless Powder,—is easily tolerated, even by the most delicate stomachs. It is invaluable in Wasting Diseases, in Convalescence from Exhausting Diseases, and is especially indicated in cases of Children of Backward Development.

SOMATOSE is well borne when no other aliment can be administered. It is also of the greatest service in cases requiring rectal alimentation.

SOMATOSE has been found invaluable in the uncontrollable vomiting of pregnant women and in vomiting following the administration of chloroform.

SOMATOSE is indicated in all conditions where an invigorating and easily absorbed food is required. With the aid of SOMATOSE it is possible to tide the patient over critical periods, since it is capable of acting for a long time as a complete substitute for other nitrogenous foods.

ADULT DOSE: One teaspoonful three times a day, in milk, soup, coffee, cocoa, &c.

The following is the Analysis of SOMATOSE as obtained by Goldman:—

Water	9·20
Total Nitrogen	12·84
Albumoses...	77·85
Peptone	2·20
Ash	6·78

IRON-SOMATOSE

(Ferro-Somatose).—An excellent tonic, containing the albuminous substances of the meat (albumoses) organically combined with Iron in the proportion of 2 per cent. of the latter. Under the use of Iron Somatose the weight of the body is increased and the amount of hæmoglobin is augmented. Iron Somatose combines in a most suitable way the well-known and appreciated properties of Somatose with a good Iron preparation.

SPECIAL INDICATIONS: Chlorosis and Anæmia. DAILY DOSE: 75 to 150 grains.

MILK-SOMATOSE

(Lacto-Somatose).—A strength-giving food containing the albuminous matter (albumoses) of the Milk, with 5 per cent. of Tannic Acid in chemical combination. The chief indications for Milk-Somatose are the various chronic maladies of the digestive organs, and especially those disturbances of digestion which, as in Enteroptosis and Anæmia, can be referred to the atonic condition of the muscular organs of the stomach. Milk-Somatose is a good flesh-forming preparation, without irritation, and slightly astringent with patients of weak or diseased digestive organs. In the case of Typhus maladies it is of great value.

Samples and Literature can be had on application to the Wholesale Depôt for all Bayer's Drug Specialities:—

BAYER'S
PHARMACEUTICAL SPECIALITIES

TRIONAL. *(Diethylsulfonmethylethylmethan).*—A most reliable and quickly acting hypnotic of the Sulphonal group. In simple insomnia Trional will produce sleep with absolute certainty in from fifteen to thirty minutes. Has no influence on the heart, respiration, or temperature.

DOSE: From 15 to 30 grains. Best administered in a cupful of hot liquid, or in aerated water, when a considerably smaller dose suffices.

TANNIGEN. *(Acetyl of Tannin.)*—A most valuable remedy in cases of Acute and Chronic Diarrhœa, and invaluable for the Summer Diarrhœa of Children. Tasteless and Odourless. Passes through the stomach entirely unchanged, decomposition only occurring in the intestines.

DOSE FOR CHILDREN: 2 to 5 grains.
DOSE FOR ADULTS: 8 grains every three hours.

TANNOPINE. *(Hexamethylene-tetramin Tannin).*—A New Intestinal Astringent. Has an excellent effect, without secondary phenomena, in all the various kinds of Enteritis. Has given especially good results in cases of Tuberculous Inflammation of the Bowels, in cases of Non-Tuberculous Subacute and Chronic Intestinal Inflammation, and also in cases of Typhoid.

DOSE FOR CHILDREN: 3 to 10 grains.
DOSE FOR ADULTS: 16 grains, two to four times daily.

SALOPHEN. *(Acetyl-paro-amydosalol).*—The best substitute for Salicylate of Sodium, as it acts quite as promptly, but without any of the unpleasant after-effects of the latter. Its special indication is Acute Articular Rheumatism. It is invaluable for Influenza, Migraine, &c.

DOSE: 16 to 24 grains three or four times a day.

LYCETOL. *(Tartrate of Di-Methyl-Piperazine).*—Combines the Uric Acid solvent properties of Piperazine, with the diuretic properties of Tartaric Acid. Invaluable in all cases of the Uric Acid Diathesis.

DOSE: 16 to 32 grains daily. Best administered in aerated waters, such as Seltzer, &c., or in granular effervescing form. (Effervescing Lycetol: Messrs. A. Bishop & Sons, Ltd.)

IODOTHYRINE. The active principle of the Thyroid Gland. A stable product containing a definite amount of the Iodine compound which forms the active principle of the Gland. Iodothyrine acts more quickly than either the fresh or dried gland substance. It is a preparation of perfectly definite composition, stable and permanent.

ADULT DOSE: 5 grains two to eight times a day.

EUROPHEN. *(Isobutylorthocresoliodide.)*—A perfect substitute for Iodoform. Odourless and non-toxic. Has a specific gravity five times less than that of Iodoform. Non-irritating and does not produce a rash. Adheres closely to mucous surfaces. Specially indicated in Syphilitic Diseases, Gynæcology, Burns and Bedsores, Eye, Ear, Throat, and Nose Affections, &c., &c.

ARISTOL. An Iodine Derivative containing 48% of Iodine. Is an ideal Cicatrisant, forming an absolutely unirritating covering over the surfaces on which it is placed, under which the processes of granulation and cicatrization proceed with extraordinary rapidity. It is a convenient, Non-Irritating and Effective Antiseptic Dressing in General Surgery, Dentistry, Gynæcology, Diseases of Eye, Ear, and Nose. In the treatment of Burns Aristol has proved to be of the greatest value, its antiseptic and healing properties being specially marked.

PROTARGOL. A new silver preparation for the treatment of Gonorrhœa, containing 8% of silver, easily soluble in warm or cold water. Has a better penetrating effect on the tissues than any other known silver preparation. Non-irritating. Usual strength of solution, ¼ to 2%. An excellent antiseptic in the treatment of Wounds. Of the greatest possible service in Ocular Therapeutics.

PHENACETINE-BAYER, SULPHONAL-BAYER, PIPERAZINE-BAYER, SALOL-BAYER, SOMATOSE, IRON SOMATOSE, MILK SOMATOSE, ANALGEN, LOSOPHAN, TETRONAL, &c.

Samples and Literature can be had on application to the Wholesale Depôt for all Bayer's Drug Specialities:—

Duotal (Guaiacol Carbonate)
Creosotal (Creosote Carbonate)

For the Treatment of Tuberculosis, Chronic Intestinal Diseases, Enteric Fever, &c.

While possessing the purely curative action of beechwood creosote and guaiacol, Creosotal and Guaiacol Carbonate have absolutely no caustic effects. The tolerance displayed to these two carbonates depends on:

1. **The absence of caustic and poisonous properties.**
2. **The absence of the intensely nauseous creosote taste and odour.**
3. **The fact that resorption takes place, not in the stomach, but in the intestines.**

Guaiacol Carbonate and Creosotal act *continuously and mildly* on the digestive tract and the entire organism. This continuous absorption is a necessary condition for their therapeutic effect. Disassociation takes place slowly in the intestines; and, unlike other antiseptics, *the Carbonates are distributed over the whole duodenum, jejunum, and ileum.* While creosote and liquid guaiacol injure the digestive tract by causing chronic inflammation of its mucous membrane, Creosote Carbonate and Guaiacol Carbonate tone it up and stimulate it.

We beg to draw attention to Von Heyden's Preparations:—

ACTOL (Crede's Lactate of Silver.)
ANTISEPTIC CREDE (Citrate of Silver).
APOLYSIN.
GUAIACOL, crist and liquid.
ORPHOL (Betanaphtol-Bismuth.)
XEROFORM (Tribromphenol-Bismuth.)
SOLVEOL.
UNGUENTUM CREDE (Ointment of soluble metallic silver).

FREE SAMPLES and LITERATURE are sent on application to
Sole Agents in England—**BURGOYNE, BURBIDGES & CO., 12 & 16, Coleman Street, London, E.C**

PROTARGOL.

A new Silver Preparation, highly efficacious in the treatment of Gonorrhœa, and most strongly recommended as an Antiseptic Wound Healer. PROTARGOL contains 8 per cent. of silver, and is easily soluble in cold or warm water, is non-irritating, and possesses a better penetrating effect on the tissues than any other known silver preparation. PROTARGOL is a chemical compound of silver and a protein substance. Its solution is not precipitated by albumen, chloride of sodium, or diluted hydrochloric acid.

Dr. BENARIO, of Frankfort, declares that PROTARGOL possesses high bactericidal properties, and is therefore excellent for the treatment of Wounds. Professor NEISSER, of Breslau, states his opinion that PROTARGOL is the best, the safest, and the quickest remedy he has yet employed in the treatment of Gonorrhœa. An eminent surgeon, in "THE PRACTITIONER" for March, confirms, so far as his experiences go, the favourable opinion expressed by NEISSER, especially with reference to its powerful anti-bactericidal properties. The usual strength of the solution for injection is ¼ to 2 per cent.

SAMPLES and LITERATURE can be had on application to the Wholesale Depôts for all Bayer's Drug Specialities—

UTERINE DISEASES.

I am much pleased with ALETRIS CORDIAL as a remedy in uterine diseases. I have been in constant practice for more than half a century, and have used the aletris farinosa most of the time. When I learned the composition of the ALETRIS CORDIAL (Rio Chem. Co.) I inferred at once that it would prove a very good uterine tonic, and find it is just the thing. Following is a case in which I used ALETRIS CORDIAL: Mrs. C., aged 33 years, had been suffering since confinement, some two years since, with leucorrhea, more or less most of the time and frequently quite profuse. I have treated her with ordinary remedies, such as tonics internally and astringent injections, with variable results, but never entirely relieving the leucorrhea. Her general health suffered less than common in such persistent cases. Some time since I made a more critical examination, and found preternatural redness of whole vaginal cavity from labia to uterus; the cervix uteri and the os tumified and sensitive to touch, as also the abdomen, especially over the ovaries; cold feet, hot head, debility and nervous exhaustion, odorous urine, itching of the vulva, etc. I used S. H. KENNEDY'S EXT. PINUS CANADENSIS as an injection and put the patient on ALETRIS CORDIAL. By the time the first bottle was used, the disease was about cured. The leucorrheal discharge ceased and the redness, etc., much diminished. I attribute her speedy relief to the ALETRIS CORDIAL, for all other applications had been persistently tested with but little benefit. I expected the ALETRIS CORDIAL to tone up the weakened womb, but supposed something more specific would be required to subdue the irritation and subacute inflammation of the vagina. JOS. S. BURR, M. D., Leesville, O.

I had under my treatment a lady, Mrs. H., 36 years of age, married twelve years, no children, who had suffered for twenty years with painful and irregular menstruation, followed by leucorrhea and nervous hysteria at times. She had tried all kinds of drugs, but not receiving any benefit from them, consulted a number of physicians, but also without effect. The 14th of April last, she became one of my patients, and I prescribed the usual formulas which were carefully prepared at my own dispensary, but to her and my regret only gained momentary benefit. I concluded to make a trial of the following prescription:

R. Celerina .....8 ounces.
ALETRIS CORDIAL.....8 ounces.
M. Sig. Two teaspoonfuls half an hour before meals.

For injection I prescribed one part S. H. KENNEDY'S WHITE EXTRACT PINUS CANADENSIS with nine parts of water, three times a day. The result has been surprising. I wanted the lady to continue the medicines, but Mrs. H., insisted upon not doing it, for she claimed that having regained her youthful health and vigor, she would need no more medicine at present. C. A. BRUEGMANN, M. D., Marysville, Neb.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

The above Preparation is prepared exclusively for the prescriptions of Medical Men. A sample will be sent free to any Medical Man who wishes to test it, on application to

RIO CHEMICAL CO., 36, Basinghall Street, E.C.

Address in Psychological Medicine

ON

MODERN CONCEPTIONS OF THE ETIOLOGY OF INSANITY.

Delivered at the Annual Meeting of the British Medical Association at Edinburgh, July, 1898,

BY SIR JOHN BATTY TUKE, M.D. EDIN., D.Sc. DUB.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH; HONORARY PHYSICIAN TO THE QUEEN.

MR. PRESIDENT AND GENTLEMEN,—Twice during the current decade the British Medical Association has demanded an Address in Psychological Medicine. For the first time in its history (in 1890) Sir James Crichton Browne was requested to perform this duty, and now, after a short lapse of years, a similar duty has devolved on me. This mere fact must be gratifying to the specialty we had and have the honour to represent as indicative of a growing consideration accorded to a department of medicine which till lately has, in the opinion of many, held a somewhat doubtful position in the realm of the medical sciences. It may be suggested that there is "a sweet reasonableness" in the demand for addresses on this subject during the current decade, for during the corresponding period of last century vast changes were brought about in the principles governing the management of the insane in France and Great Britain, and that therefore it has been deemed desirable to commemorate the centenary of a beneficent revolution. But I doubt much whether this epochal consideration has had much to do with the matter, nor do I think that the requests of your council for addresses on the subject have been prompted by social considerations affecting the general public directly.

Doubtless the rapidly-increasing incubus of lunacy is seriously complicating Poor-law administration, but the question of relief from its pressure is not one which can be referred to the opinion of a single individual. It is a big question with many ramifications, social, medical, and legal, and I take this opportunity of suggesting that its consideration might be referred to a mixed commission appointed by this great Association consisting of authorities in lunacy, representatives from the general profession, lawyers, and Poor-law administrators. It is possible that such a commission might arrive at valuable general conclusions which might influence future policy and arrest the haphazard drifting one which at present obtains. I believe the actual reason for the requests for these addresses to be that the profession at large is alive to the fact that so-called psychological medicine is becoming day by day more and more incorporated in general medicine and less and less a peculiar and isolated department; that with the advance of knowledge of the nervous system the glamour which hung over the general conception of insanity is becoming dissipated; and that the various phases of mental alienation are coming to be recognised as symptoms of numerous and very various morbid physical conditions. In point of fact we are drifting away from the psychological conception of insanity, from the contents of the term "mental disease," even as our ancestors drifted away from the idea of demoniacal possession. "*Nulla mens insana sed in corpore insano*" expresses the principle which is, to say the least, beginning to regulate our conception and our practice in respect of all the conditions comprised under the generic term "insanity." It may be freely admitted that the proposition was enunciated centuries ago, but the theories of the connexion between diseases of the general system and mental symptoms were so loose as to exercise little or no influence on principles or practice. The popular conception of insanity a hundred years ago was to all intents and purposes psychological; at the best it was a rude mixture of a pseudo-psychology and a pseudo-pathology identical with what we find in the pages of Burton, and the views of the medical profession, with a few isolated exceptions, were not much further extended. I hold it to be my duty to-day, so far as time admits, to review the course of events which have served to divert the current of opinion, to indicate the palpable indications of change, and the bearings such change has had, is now having, and may in the future have, on the treatment of the insanities. In so doing I can only hope to sketch the subject in the broadest manner, marking merely the main historical points, and reviewing it from the standpoint of one who for forty years has studied the progress of events.

STUDY OF THE INSANITIES.

It was inevitable that from the earliest down to quite recent times the study of the insanities should be carried out on psychological lines. The prominence of the mental symptoms asserted itself and cases of insanity were classified under the terms "mania," "melancholia," and "dementia." Notwithstanding that these so-called forms were based on mere external appearances, that their common characters were so loose that to say a case belonged to any one of them gave no further indication than could be derived from superficial observation of the case itself, these terms assumed the proportion of diseases. The symptom was the essence of the case and the underlying causating condition was ignored. Undoubtedly to the public and the lawyer the mental symptoms must always be the essence of the case, but to the physician it was not. He has to go further back and seek for the *fons et origo mali*. To him the underlying morbid condition is the essence of the case. Still, in the hands of Pinel and his school the psychological method of study subserved important purposes, the most important of which was the expiscation of general paralysis of the insane out of the general mass, accomplished by the keen clinical observations of Bayle and Calmeil. But the evils of concentration on psychology are well illustrated by the instance of Pinel himself. He, a man of high scientific attainments, a mathematician, an ardent student, and the translator of the works of Cullen, extended to the insanities the analytic method which he held should govern the study of all diseases, and accordingly he not only set aside as useless the observations of Haller and Portal, but reconstituted the Hippocratic classes of insanity as concrete pathological entities. From the acknowledged position attained by Pinel in scientific medicine by the force of character which showed itself in the bold steps he took to improve the management and treatment of the insane, and from the reputation he most justly gained from the beneficent movement, his influence has been and is even now great on the study of insanity. Most of his pupils followed his line of observation, and down to the present day mania, melancholia, and dementia hold practically the position of pathological entities in the mind of the public, of the lawyer, and of no small part of the medical profession. This undivided adherence to the psychological principle of study led to "an undue love of minute detail" and consequently to undue extension. Instances in which intellectual deficiencies were not so apparent as changes in feeling and conduct were designated cases of "moral insanity," with such sub-classes as pyromania, erotomania, kleptomania, homicidal and suicidal mania, and so on, irrespective of the clinical observation that no case of insanity exists without moral aberration, and that in those cases in which moral obliquity is most prominent the intellectual faculty is also weakened, inasmuch as the patient is not able to recognise the nature of his immoral acts or weigh their consequences. Thus confusion became worse confounded and fallacies arose within the psychological conception itself. It had, moreover, a further result in the production of a conflict between law and medicine, the consideration of which, interesting as it is, the limits of this address do not permit of. All that need now be said is that the assumption of a clinico-psychological position on the part of the physician in medico-legal cases served to intensify in his mind the importance of the psychological nosology of insanity. This becomes all the more evident when we turn to the work of such authorities as Stahl, Jacobi, Sauvage, and Cullen, who brought to bear on the subject various principles of study of disease at large, yet when they proceeded to classification of so-called mental diseases reverted to metaphysical or psychological considerations. Accordingly so-called psychiatric medicine held a peculiar and isolated position and, as Griesinger said, "its study was supposed to be distinguished by some difficulties *sui generis*." It is only during the last thirty-five years that the study of the insanities has ceased to be so distinguished, or at least

Digitized by Google

that scientific data have been afforded which should prevent it being so distinguished, data which, although still far from perfect, have afforded starting points to the psychiatric physician for the scientific study of his subject. In passing let me say that I deprecate the use of the word psychiatric, but it has become so commonly employed as indicative of the study of morbid mental action as to render its provisional use convenient.

STATE OF KNOWLEDGE IN 1864.

It is of interest and importance to contrast the state of knowledge of the anatomy and physiology of the cerebral hemispheres in 1864 with that of 1898. Up to the former year even the rough naked-eye anatomy of the convolutions was chaotic, only some two or three gyri being recognised as distinct anatomical landmarks, and it was only then that Gratiolet reduced them to system, demonstrated their orderly arrangement, and propounded a nomenclature which, with certain modifications, is in use to-day. The position at the same time as regards minute anatomy, and therefore as regards physiology, is best illustrated by a quotation from the sixth edition of Carpenter's "Principles of Human Physiology." He therein states: "It is a point specially worthy of note that no sensory nerves terminate directly in the cerebrum, nor do any motor nerves issue from it; and that there seems a strong probability that there is not a direct continuity between all or any of the nerve fibres distributed to the body and the medullary substance of the cerebrum. For whilst the nerves of 'special' sense have their own ganglionic centres it cannot be shown that the nervous fibres of 'general' sense, which either enter the cranium as part of the cephalic nerves or which pass up from the spinal cord, have any higher destination than the thalami optici. So the motor fibres which pass forth from the cranium, either into the cephalic nerve-trunks or into the motor columns of the spinal cord, though commonly designated as cerebral, cannot be certainly said to have a higher origin than the corpora striata. And we shall find strong physiological as well as anatomical ground for the belief that the cerebrum has no communication with the external world otherwise than by its connexion with sensori-motor apparatus; and that even the movements which are usually designated as 'voluntary' are only so as regards their original source, the stimulus which calls the muscles into contraction being even then immediately issued from the cranio-spinal axis as it is in the movements prompted by the reflex stimulation of an external impression." This was the opinion of the recognised physiological writer of the day, who, in the absence of anatomical data, set aside the results of ablation of the hemispheres as demonstrated by Flourens and disregarded the inductions of Laycock bearing on what he termed the reflex function of the hemispherical ganglia. The gap was bridged by the ingenious methods of cutting and staining devised by Gerlach and Lockhart Clarke, who were the pioneers of a system of research which, developed in the hands of Meynert, Max Schultze, Rudolph Wagner, Kölliker, Gowers, Weigert, Bevan Lewis, Golgi, Ramon y Cajal, Nissl, Flechsig, and others, revealed paths of conduction between the outer world and the regions of highest cerebral function, between hemisphere and hemisphere, between convolution and convolution, and between the tracts of the special organs of sense. Let me advise those amongst you who desire to fully recognise the altered state of things to keep in mind the statement of Carpenter just quoted and then to study Déjerine's "Centres Nerveux," the last edition of Kölliker's "Handbuch der Gewebelehre des Menschen," or the more readily accessible "Text-book of Physiology" by Michael Foster. In the last edition of this most charming work the part written in conjunction with Sherrington sets before the student a wonderful panorama of brain connexions, paths of conduction between organs without and within the skull, between the various organs of the brain itself, and between various parts of the same encephalic organ. Although the authors never overstep the physiological limit it is difficult for the reader to avoid, whilst studying the relations of the mechanism by which impulses are distributed, the construction of schemes which for the moment seem to make it remotely feasible to conceive how it might be possible to account for the transmutation of external impulses into states of consciousness. Need it be said that his dreams are short and that he wakes to the fact that he is vainly seeking to think of the unthinkable and that his sphere is limited to the study of structures, the destruction or implication of which renders mental activities impossible or imperfect. The very brilliance of the anatomical demonstrations and of the physiological deductions emphasise the wide gaps in our knowledge. Large areas of the cortex exist to which no system of experimentation has been able to assign or even to suggest special functions. But Flechsig has of late asserted that certain of these unnamed regions in the brain may be filled in, for he has arrived at the conclusion, founded on a series of anatomical, physiological, pathological, and clinical observations, that certain of the cortical areas on the superior and frontal aspects constitute the material "antecedents" of mental activities, in that they are the areas in which the stimuli of the various sense spheres are associated. Great as has been the work of the anatomist that of the physiological pathologist has been equally important. Hughlings Jackson's name must ever hold the foremost place in this department of science, and I am sure Fritsch, Hitzig, Ferrier, and Gowers would be the first to acknowledge that his induction opened up that field of inquiry which has been of such importance to the study of nervous physiology and pathology. It is not necessary for the present purpose to do more than allude to the observations of these authors as they are matters of common knowledge, and it is impossible to-day to do more than allude to the contributions of the experimental pathologist, the embryologist, the physicist, the chemist, and the comparative anatomist, all of which converging expand our views on the general question.

THE PSYCHO-PHYSICAL SCHOOL.

The physiologists of the psycho-physical school which arose as a result of scientific developments advanced the study of psychology so far as they ranged scientific data so as to add to the "provisional body of propositions" about states of mind necessary for their philosophy. Whether our knowledge of states of mind has been materially increased by the lucubrations of this school is open to question, but there can be no doubt that the views, not only of the physiologist, but of all thinking men, have been enlarged by the application of the philosophic mind to the scientific position. Were it only that the world has had placed before it the proposition that the essence of mental life and the essence of bodily life are the same—namely, the adjustment of inner to outer relations—great gain has accrued to science and philosophy. But I verily believe that the change of conception of the nature of the insanities is much more due to the establishment of scientific data bearing on the antecedents of mental action than to the generalisations of the philosopher as to mental activities. Remember we are dealing with the mental attitude of a profession which deals with material and which till lately, so far as the cerebral material is concerned, had slight scientific knowledge. Gradually—no, I should say rapidly—perhaps too rapidly for complete assimilation—there has been presented to the physician knowledge of a cerebral apparatus on which he is warranted in basing working hypotheses and practice. Until that apparatus was demonstrated he could not assert, except as an assumption, the fundamental physiological principle that mental action is a function of connexion, or the pathological corollary that interruption of connexion is the cause of impaired mental action. Given those starting points he can work in the same atmosphere as a brother physician. That atmosphere may not be—nay, is not—so clear as that of his colleague; he may still see through a glass darkly; but what he does see is a revelation to him which could not have been afforded by the study of a philosophy which, except in certain of its provisional propositions, is not cognate to medicine. Time to-day will only serve to allude to the observation around which all others centre. That, to my mind, is the demonstration of mechanism by which impulses are carried from the periphery to the cortex and from the cortex to the periphery. We know that series of fibres exist which, starting from the entire surface of the body, the muscles, and from the mucous membranes, are collected in the spinal cord and pass upwards to the optic thalami, whence—as demonstrated by Flechsig whose observations have been confirmed experimentally by Ferrier and Aldren Turner—they are distributed in three systems to the cortex. We will deal with only one of these "sensory" systems—that which passes directly to the Rolandic cortex without forming connexions in their upward course with any other system of fibres. In the external layers of the grey matter these fibres come into relation with the dendrites of the pyramidal cells, but there is no anatomical continuity

Digitized by Google

between the sensory fibres and the dendrons; they transfer impulses by contact. It is contended by certain observers that the liberation of energy takes place in the dendrons, which by their gemmulæ are in close contact with the dendrons of other cells, forming what Foster terms "synapses." Be this as it may impulses descend to the cell bodies, through which certain of the fibrils of the dendron pass to the descending axon—till lately spoken of as the axis cylinder—the fibrils of which are distributed to the periphery, throwing off collaterals to remote areas of the cortex. In order to obtain and maintain the conception of the mechanism of a circuit it might be well not to restrict the term "neuron" to the cell body and its dendritic processes, but to include in the term the ascending conducting apparatus, the cell body, and the spinal, cerebellar, and cerebral distributing arcs, and to regard the whole apparatus as a physiological if not an anatomical unit.

It is not necessary for our present purpose to consider where and how the transmutation of peripheral impulses takes place, but it is of importance to emphasise the statement that impulses are not generated in the cell body. As Gowers says, the old battery idea must be thrown aside. It may be regarded as the "vital centre" of the neuron, and making allowances for the possible action of the dendrons it may be held to be a receiver, conservator, and transmutator of energy, and a liberator and distributor of energy by means of its synapses with other pyramidal cells, and, with what is of supreme importance, with association cells. But all impulses come from without, a fact which must have important bearings on the question of the adjustment of outer to inner relations. Although the neuron has been spoken of as an organ it may be as well to state, for the benefit of any layman who may be present, that the neurons can be counted by millions; but anyone can realise that an almost unappreciable number of organs must exist for the reception and distribution of the constant and continuous flood of impulses which streams from without inwards to the brain. It is as difficult to estimate the influence of the developments of knowledge of the nervous system on the individual general physician as it is to gauge the influence of bacteriology. Our acquaintance with both these subjects is a recent acquisition. The latter is a new science, and I believe I am right in saying that in the case of many of us only its outlines are present with us. But its principles pervade the method of thought of the whole profession. So with the study of the minute anatomy of the brain; none but experts can be expected to be acquainted with the full details of its anatomy, but the great leading facts as to structure and the facts, theories, and warrantable assumptions as to its actions have operated, and continue to operate, on the views of the specialty at large. Its members, knowing that they have a mechanism to deal with, solution of the continuity of which in any part of its course may affect its function, have a scientific foundation for the study of the morbific influences productive of interruption of connexion. A strong indication of the awakening of the scientific spirit is afforded by the earnestness with which the study of the morbid anatomy of the brain is being prosecuted by the psychiatrist all the world over. Shortly after methods of cutting and staining microscopic sections of nervous structure were promulgated the rough turning over of the soil was begun. Naturally, in dealing with what was then an occult subject certain errors of observation and deduction were made; still, the fact was elucidated that marked departures from health were to be found by microscopic examination of the brains of persons dying insane. Steady labour, however, soon had its effects, and the results were embodied in the work of Bevan Lewis, in which not only were lesions described in the mass, but differentiation of special lesions in connexion with certain classes of insanity were demonstrated. Since the publication of that book our knowledge of the minute anatomy of the brain has been considerably increased and with it our knowledge of its lesions and our appreciation of their significance. Let me allude to two instances of this. First, the demonstration of the loss of gemulæ of dendrites under the action of disease, the organs which we have a right to believe have important conducting functions; and, secondly, to changes in the cell bodies, the significance of which was misinterpreted so long as it was regarded as an originator of impulse. Now that we understand that one at least of its functions is control over the nourishment of the great neuron the pathological value of its lesions assumes different but still very important proportions, inasmuch as the consequences of impaired trophesis, or interruption of continuity must be sought for in the synapses or in other parts of the paths of conduction.

THE PATHOLOGY OF INSANITY.

The value of research into morbid cerebral anatomy made itself so strongly felt that laboratories were established in many asylums, and eventually the County Council of London were so deeply impressed by the importance of the subject that they instituted a thoroughly equipped laboratory for the systematic study of the pathology of insanity, placing it in charge of that able and experienced physiologist and pathologist Dr. Mott. The work he has already accomplished is of great interest and value and we may confidently anticipate rapid progress in this department of science as the result of his labours. Scotland has followed suit. An association of asylums has been formed for the same purpose. Assisted by the Royal College of Physicians of Edinburgh suitable premises have been provided and systematic work is being prosecuted under Dr. Ford Robertson, one of whose most important duties is the instruction of assistant medical officers of asylums in methods of research. Similar institutions have been erected in the United States and if I merely refer to the observations of Van Giessen of New York, of Berkeley of Johns Hopkins University, and of Hodge of the Clark University, evidence is afforded that important scientific results have been already obtained, bearing, not only on morbid anatomy, but on physiology and normal anatomy. Contributions flow in from Germany, Italy, France, and Russia, and it may be truly said that the psychiatrist all the scientific world over is alive to the necessity of tracing the lesions productive of solutions of continuity as an essential part of the pathology of the insanities. In this connexion I may allude to the importance attached to science by the Medico-Psychological Association of Great Britain and Ireland. This association holds examinations for the certification of practitioners already conversant with insanity. Whilst demanding evidence of knowledge of the normal and morbid anatomy of the nervous centres it excludes psychology in any form as a subject of examination. I do not say this exclusion is to be commended, more especially as it relates to physiological psychology; it is only adduced as an example of the prominence given to pathology. As a consequence of this system of study a vast change has come over the aspect of psychiatric literature. The journals of the day, instead of dealing largely with analyses of the mental condition of real or imaginary persons with abstract considerations and mere clinical details, are now mainly occupied by papers of a strictly scientific character bearing on the production of neuroses, and the reports of cases are rarely confined to a mere description of symptoms, and in one particular instance — the monumental work of Bevan Lewis—we have the study of the insanities preluded by a systematic account of the cerebral apparatus instead of by an attempt to analyse mind, which was the time-honoured introduction to works on mental aberration. But the all-important question remains to be answered, What effect has the change in the principles of study had on general pathology, practice, and treatment? As regards general pathology the evidence is manifold, but I must confine myself to two illustrations. In former times the theory of the effect of the mind on the body held a foremost place and gave rise to many misconceptions. For instance, the general degradation of the system, the complications in the intestinal and reproductive systems, which are such marked and important symptoms in many of the insanities, were regarded either as the results of abnormal mental action or as its cause. Now that we recognise that the brain exercises trophesic functions over all the organs of the body we are alive to the fact that such degradations are referable to imperfect brain action, that they are secondary on the reduction of its nourishing action, and are to be treated accordingly. We connote the well-known results of experimental ablation of the cerebral hemispheres with the evidence of diseased action observable in those regions amongst the insane. Another evidence of change is afforded by the acceptance and extension by the psychiatrist of the principle that all mental symptoms are produced by the action of the same causes of disease which act in other systems than the nervous. In the absence, which I believe will be but temporary, of a nosology of the insanities founded on

Digitized by Google

morbid anatomy we find him tracing the history of each etiological class, studying each and all on the same lines as the hospital physician follows in the case of ordinary disease. He is no longer content with the rudimentary classification of the insanities; he disregards the six "Disorders of the Intellect" set forth in the "Official Nomenclature of Diseases," published in 1871, and associates with and qualifies each symptom by an etiological term indicative of the morbific agency which has been potential in its production. Thus he is brought into close contact with general medicine and is asserting, in the words of the far-seeing Griesinger, that "diseases of the nervous system form one inseparable whole, of which the so-called mental diseases form only a certain moderate proportion."

TREATMENT OF THE INSANE.

The psychiatrist has influenced public opinion in this respect very markedly. In most of the recently erected institutions for the insane at home and abroad we find separate hospitals provided for the treatment of recent and acute cases. This surely marks the reduction of theory to practice. Instead of the subject of a recent attack of insanity being mixed up with the residuum of chronic cases he is placed in a separate institution where he is submitted to systematic treatment on thoroughly hospital principles. The extreme delicacy of the brain structure demands early and assiduous medical treatment in order to prevent disintegration and destruction of tissue; and the psychiatrist has so forced this on the mind of lay asylum authorities as to have induced them to place at their disposal hospitals suitable for this purpose. This to my mind illustrates how widely diffused the change of feeling in regard to the insanities has become extended. But even with such appliances many of those working amongst the insane are heavily handicapped, as no provision is made by the public for the treatment of cases in the initial stages. Statistics show that the increase of chronic lunatics occurs amongst the poorer classes of society and not amongst the rich. I believe this to be due to the latter being able to place members of their class showing indications of incipient insanity under systematic treatment at home during the prodromal stage, whilst the former are compelled to allow matters to drift till cases become more or less confirmed. We know that if we exclude general paralysis and epileptic insanity from consideration at least 80 per cent. of recent cases are amenable to treatment. But such treatment is necessarily costly as it involves nursing, possible change of residence, and continuous medical attendance. This is out of the power of the poor to obtain. All general hospitals shut their doors against persons suspected of insanity on the ground that the asylum is the proper place for their treatment. The asylums, however, cannot receive cases until the symptoms are so far advanced as to warrant certification and in England especially the procedure for the transmission of insane persons to asylums is so absurdly cumbrous as to prevent many persons being placed under treatment until such time as the probabilities of recovery are seriously lessened or the case is hopeless. How this state of matters can be improved is one of the questions to be taken up by the commission I have suggested. Some relief may be obtained by the inclusion of the study of the insanities in the five years' curriculum of study demanded of the rising generations by the General Medical Council. If teachers conduct their courses of instruction on the general principles which govern the teaching of medicine the general practitioner will soon be found treating the insanities as he does everyday disease, and we may fairly anticipate a reduction of the number of cases relegated to asylums as a consequence of early and rational treatment. I have merely touched the fringe of the subject. I may plead *inopem me copia fecit*, but if I have been able to indicate, however feebly, that the members of the psychiatric specialty are with you in all things scientific and practical the object of this address has been attained.

ROYAL SOUTH HANTS INFIRMARY. — The governors recently met to consider the question of a new wing to the infirmary in commemoration of the Queen's Diamond Jubilee. The Mayor's Fund falling short of the amount expected, Mr. W. Garton, a local resident, who had already given £1000, generously offered to pay the cost above what had been subscribed—about £5000—an offer which the governors accepted with thanks.

THE EFFECTS OF DRYING OF THE SOIL UPON THE PUBLIC HEALTH OF BUENOS AYRES.[1]

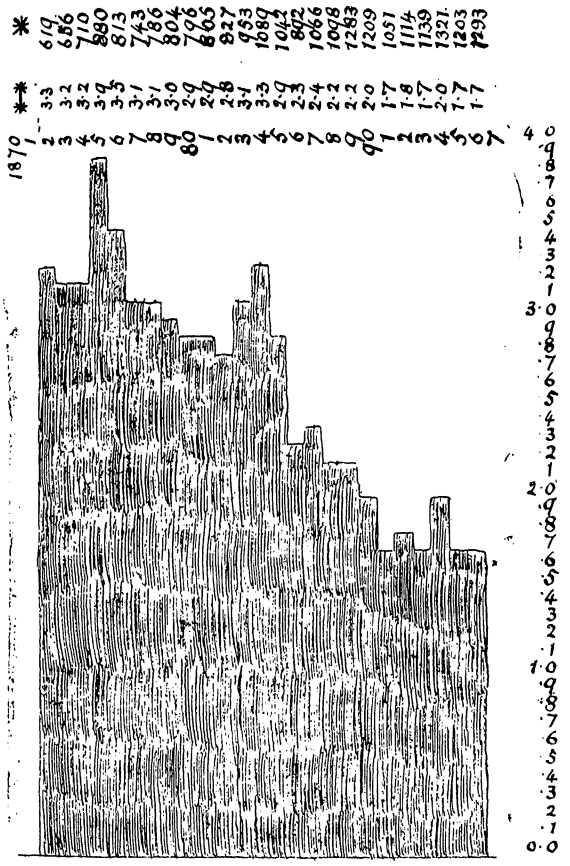
BY JAMES T. R. DAVISON, M.D. EDIN.,
FORMERLY RESIDENT PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY; MEMBER OF THE NATIONAL BOARD OF HEALTH, ARGENTINE REPUBLIC.

BUENOS AYRES, the population of which at the end of 1896 exceeded 700,000 inhabitants, possesses an extensive system of sanitary works. In that year there were over 40,000 houses provided with water from the River Plate, and an equal number of houses provided with drains; the city was also provided with works destined to remove its rainfall. These sanitary works were not all constructed at the same time. Their construction was carried out in three periods, and this has made possible the appreciation of the effects produced separately by each of the several sanitary factors which were brought into activity. In this paper I shall limit myself to the study of the effects produced by only one of the factors—that which was concerned with drying the soil.

The soil of Buenos Ayres is composed of clay and sand, with great preponderance of the former. Impermeability and retention of dampness characterise this soil. Almost every year rain falls in torrents over the city. Formerly, owing to the configuration of the ground and because at that time the rainfall lacked an easy exit, Buenos Ayres was subject to continual inundations. These inundations, which remained on a soil of the nature above described, had necessarily to give rise to its perennial dampness, and the population whose houses were built upon such a soil was left exposed to the good and ill effects connected with such a condition.

Briefly, the works destined to prevent the dampness of the soil are the following. The ordinary rain-water which falls upon the houses and streets is carried, respectively by the drains of the former and the sinks of the latter, into the collecting sewers, from which it finds its way into the intercepting sewers and thence through the great sewer into the river. The torrential rainfall takes a different course. Gathered at first as the ordinary rainfall, in its way it overflows into great storm-water conduits and is thus carried directly into the River Plate in front of the city. The works began to be constructed in 1874. First the storm-water conduits, the intercepting sewers, and a fair number of collecting sewers were made, but not until 1876 and the beginning of 1877 was the first series of street sinks (817) constructed, these sinks being destined to receive the rainfall from the streets and to thus prevent inundations, giving exit to water which before had accumulated in the city. The report of Mr. Higgins, the engineer, for this last year, referring to the purpose which these sinks already filled, says: "Although in an incomplete state they have served to save the city from various inundations." The works were suspended in 1877 and were recommenced in 1883. In 1885 the number of street sinks constructed was 2685, and in the following year 1626 new ones were made. The works were once more suspended until 1889, when the construction of house drains was begun, this part of the works having continued during several years.

In the history of the sanitary works of Buenos Ayres there are two epochs when the works destined to carry away the rainfall came into operation—in 1876 and the commencement of 1877, when 817 sinks in communication with the sewers were constructed in the streets, and in 1885 and 1886, when respectively 2685 and 1626 more were made. The system of house drains cannot be taken as an independent factor in removing the rainfall, for formerly the rain which fell on the houses was collected partly in deposits and the rest found its way to the street; now all this rain goes into the house drains, but even if it went into the streets it would not remain stagnant as before, inasmuch as the street sinks would provide for its exit.



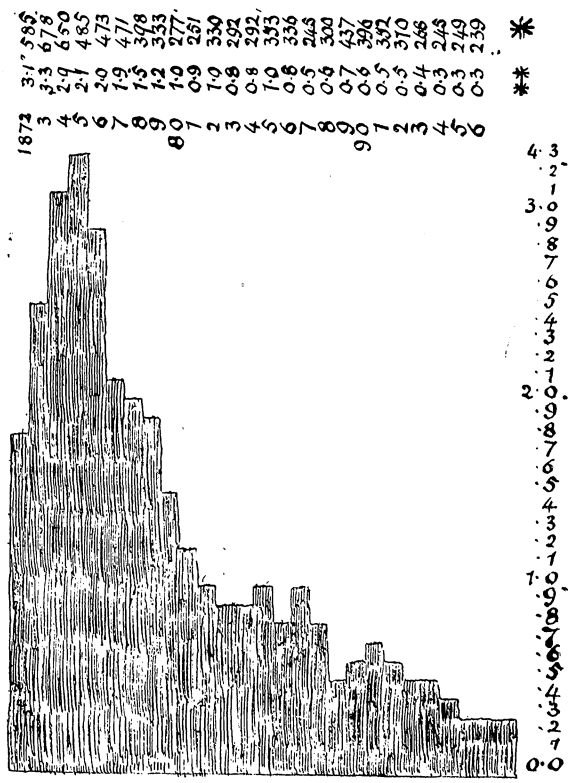
Tuberculosis.—Shortly after the year 1860, Dr. Buchanan in England and Dr. Bowditch in North America, almost

[1] A paper read at the International Congress of Hygiene and Demography held in Madrid in April, 1898.

Digitized by Google

at the same time and quite independently, discovered as the result of their investigations that tuberculosis is a disease of a damp soil, and that when this dampness diminishes tuberculosis decreases. The experience gained in Buenos Ayres entirely confirms the affirmations of these sanitarians, who have shown what is the most simple and efficacious means of ridding cities of one of the most potent factors in mortality. Fig. 1 marks the mortality from tuberculosis from

FIG. 1.



The diagram shows the prevalence of tuberculosis, pulmonary, laryngeal, and mesenteric, from the years 1872 to 1896 inclusive. The row of figures marked with an asterisk shows the absolute mortality for each year. The row marked with a double asterisk and the column to the right of the diagram show the mortality per 1000 inhabitants for each year.

1872 to 1896 calculated at so much per 1000 inhabitants. The general direction of the graphic line is one of descent, but this course is interrupted on three different occasions by elevations, a notable one in 1875 and two of lesser importance in 1884 and 1894. In this paper it is not my purpose to enter into the causes which have produced these elevations, as being foreign to the subject under discussion, but I merely wish to call attention to them so that they may be taken into account when the cause of the general descent of the line is studied, their true characters being assigned as accidental elevations in a line of general descent. The diagrammatic line belonging to 1872–73–74 marks the level of 3·3 and 3·2 per 1000 inhabitants. This represents the normal level of tuberculosis mortality in Buenos Ayres for these years. In 1875 and 1876 accidental factors caused this level to rise, and the line ascended considerably on the first of these years, and while it descended on the second it still only reached a level which was very superior to that occupied during 1872–73–74. In 1877, the factors which had produced this transitory elevation in the mortality having disappeared, the diagrammatic line descended until it occupied its former normal level and it fell even a little lower yet. In 1876 and the commencement of 1877, 817 street sinks were brought into operation, and with so much success that the engineer of the works stated in 1877 that these elements for the removal of rainfall had been the means of saving the city from several inundations. So that in 1876–77 the soil of Buenos Ayres entered into an epoch of relative dryness compared with the dampness of previous years. This relative dryness of the soil soon made itself felt in a diminution of tuberculous mortality. Already in 1877 the line had fallen, and this fall went on progressing, although slowly, until 1882. Accidental factors cause again the mortality to ascend, and in 1883 the line rises and continues to rise in 1884. These factors disappearing, the line returns to find its normal level in 1885. But that year saw the construction of 2685 street sinks, a very large number of openings destined to remove part of the rainfall which formerly stagnated in the streets. In 1886 the mortality from tuberculosis took a rapid descent. In that year the number of new street sinks was 1626. In the following year the mortality line should have undergone a further descent, but it did not; on the contrary, the graphic line was marked by an elevation, although insignificant. But in that year (1887) a law was passed extending considerably the municipal bounds, so that now large suburban areas destitute of works for the efficient removal of rainfall formed part of the city. Nevertheless, the insignificant rise in the mortality in 1887 was but transitory, for in the following year the works which had been constructed in 1885–86 reasserted their influence over the mortality from tuberculosis and the graphic line began once more to fall and continued falling until 1891, when it seems to have remained stationary, for after oscillations it always returned to the same level.

The fall in the mortality from tuberculosis in Buenos Ayres is thus related to the relative drying of the soil compared with the dampness which obtained in former years. The first works for removing the rainfall which commenced in 1876–77 produced a slow fall which lasted in a progressing scale during six years; the second and more extensive works of 1885–86 brought about a much greater fall in the same

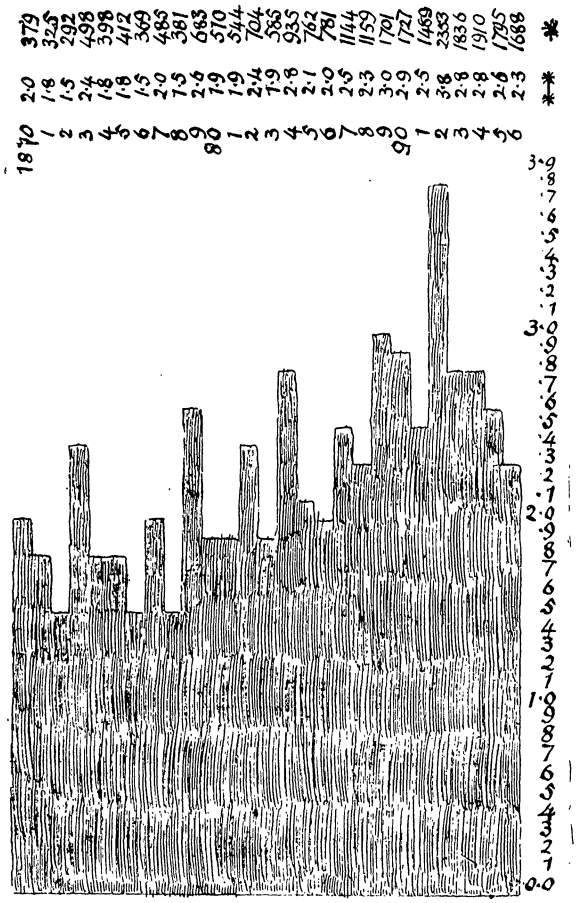
FIG. 2.

The diagram shows the prevalence of tetanus, infantile, traumatic, and spontaneous, from the year 1872 to 1896 inclusive. The figures have the same significance as in Fig. 1.

mortality—a fall which in its progressive course has also lasted six years. The level which the mortality had reached in 1896 was that which it already occupied in 1891. Since the former year there has been no further fall, and as during these last years thousands of house drains have been brought

Digitized by Google

into operation it must be concluded that this latter sanitary factor has not exercised any beneficent influence over the march of tuberculosis and that the relative drying of the soil has been the only and great factor which has saved Buenos Ayres from its once so high tuberculous mortality.



Tetanus.—Tetanus was formerly another scourge of Buenos Ayres. Fig. 2 marks the mortality from tetanus calculated at so much per 1000 inhabitants. In 1870 there was a very great inundation in the city; some persons were drowned in the streets; the cesspools filled with water and their contents flowed out and spreading over the soil polluted its surface. The mortality from tetanus, which was already high, appears to have received a great impulse from this special contamination of a damp soil, for in the following year the graphic line of mortality rose very much and this rise continued up to 1873, the descent beginning in 1874 and the line only reaching in 1877 its former level of the year 1870. It is to be noted that in the course of these years the inundations were not limited to the special one of 1870. Every year there were inundations and these served to maintain alive the flame which had been ignited by the great inundation of 1870, when the soil, besides being saturated with water, was contaminated by the contents of the cesspools which had overflowed. But already, after the first series of works destined to remove the rainfall in 1876–77, the inundations ceased to a great extent and the result of this relative drying of the soil was felt in 1878, when the line of mortality from tetanus took a sudden fall and this fall continued in a progressive sense until 1881. The line now rested at the level of 0·9 per 1000 inhabitants and this level appears to have indicated the maximum of the results obtained by the relative drying of the soil which was due to the works effected in 1876–77, for in the following year of 1882 the mortality line occupied the same position and remained there as a mean level during four years more.

The second series of works destined to remove the rainfall more completely was constructed in 1885 and 1886, when respectively 2685 and 1626 street sinks in communication with the sewers were made. Next year the mortality line from tetanus took a rapid descent. This descent, which should have continued progressively during three or four years more, was interrupted, but in 1888 the annual form of the atmospheric pressure-wave suffered oscillations which interfered with the natural ventilation of the soil, and in 1889 extensive excavations of the same in connexion with the construction of house drains were begun and the work continued for several years. When these transitory factors which interrupted the continuation of the fall of the mortality from tetanus had in great part disappeared in 1893 the mortality line reassumed its course of descent, this lasting until 1894, where the line seems to have remained, and 0·3 per 1000 inhabitants has marked the level of the mortality from tetanus in 1894–95–96.

Re-examining rapidly the graphic line of mortality from tetanus we see that when this line was seeking its former normal level after having ascended owing to a great contaminating inundation, helped by further inundations, the relative drying of the soil obtained by the works of 1876–77 caused it to descend during four consecutive years; that the mortality line then rested upon a stable level during several years, when the new works for completing the removal of the rainfall in 1885–86 caused its further descent—a descent which, although interrupted in its course through transitory factors during some years, reassumed its prolongation on the disappearance of these until in 1894 it reached the level of 0·3 per 1000 inhabitants. It is, again, to the relative drying of the soil that the population of Buenos Ayres is indebted for its marked deliverance from one of the most important factors of its mortality.

Pneumonias.—If the drying of the soil and subsoil in Buenos Ayres has resulted in a marked diminution of the mortality from tuberculosis and in a notable diminution of that from tetanus, on the other hand it has been the means of increasing the mortality from pneumonia. Fig. 3 marks the mortality of the group of pneumonias, including also broncho-pneumonias and pleuro-pneumonias. The graphic line, although subject to great oscillations, has nevertheless a direction of general ascent. The ascent does not follow a march of gradual progression, rising every one or two years; it is an ascent effected by periods of years, rising every so many years to a higher level from which it never again descends but from which it oscillates in an upward direction. Three are the levels of repose belonging to this graphic line. The first one, 1·5 per 1000 inhabitants from 1872 to 1878; the second one, 1·9 from 1879 to 1886; and the third one, 2·3 from 1887 to 1896. The first and lowest level corresponds to the time when the rainfall was allowed to remain in the city; the second and higher one to the time when the effects of the works destined to remove a good deal of the rainfall began to be felt; and the third and highest to the time when the effects of the second and more extensive series of the above works came into operation. In this group of pneumonias there are, of course, many cases which are only

FIG. 3.

The diagram shows the prevalence of pneumonia, broncho-pneumonia, and pleuro-pneumonia from the years 1870 to 1896 inclusive. The figures have the same significance as in Fig. 1.

complications of other diseases and which are altogether independent of the greater or lesser dryness of the soil, but the fact that the level of mortality of the group as a whole rises each time that a greater relative dryness of the soil is obtained is a proof that in this group there must exist a sub-group of pneumonias due to some micro-organism which resides in the soil and the development of which is favoured by a relative dryness of the same.

The experience of Buenos Ayres has permitted the study of the results obtained separately by each of the factors which have been brought into play through the construction of sanitary works. As far as the effects on tuberculosis resulting from the relative drying of an impermeable clay soil go our experience corroborates the teaching of Buchanan and Bowditch, who showed that in that dryness we possess the most formidable weapon to combat that great enemy of the human species. Touching tetanus the effects of the relative drying of the soil have been even more marked than in the case of tuberculosis. And, lastly, regarding pneumonias, the relation between the increase of this group of diseases is too evident to be ascribed to mere coincidence. Several have been the observers who in different countries have noted this relation, but their conclusions have been impugned and

Digitized by Google

sometimes with statistics which have been gathered monthly. The question is yet *sub judice*. The statistics which I adduce in this paper have the value that they cover an epoch of a quarter of a century, and they have even greater value because this epoch includes periods in which the construction of the sanitary works was carried out separately in its different elements, so that the effects of these upon the public health could easily be observed. Changes in the subsoil take place with great slowness and their effects upon the public health are likewise slow and *prolonged*. In order to study correctly the relation between subsoil and public health years and not months must cover the periods of observation.

Buenos Ayres.

DISSECTING ANEURYSM.[1]

BY JAMES B. COLEMAN, M.D. R.U.I., M.R.C.P. IREL.,
PHYSICIAN TO THE RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS; TO THE NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND; AND TO THE CHILDREN'S HOSPITAL, DUBLIN.

THE term "dissecting aneurysm" is applied to cases in which a partial rupture of the inner tunics of an artery allows the blood to become diffused between the coats of the vessel. Having regard to the difference of opinion which exists as to the author of the original description of this very remarkable affection the following extract from Dr. Peacock's "Report on Cases of Dissecting Aneurysm"[2] may be of interest: "It has generally been supposed that Laennec was the first writer who applied the term 'dissecting' to this form of aneurysm, but it has been recently shown by M. Broca that M. Maunoir employed the same designation and clearly described the formation of aneurysms of this kind in his work published in 1802. A characteristic case is also related by Mr. Allan Burns in his work on 'Diseases of the Heart and Aneurysm,' published in 1809." Shekelton[3] published two cases of dissecting aneurysm in 1822, and the preparations are to be seen in the Museum of the Royal College of Surgeons in Ireland. Erichsen, in the earlier editions of his "Science and Art of Surgery," incorrectly refers to this variety of aneurysm as "originally described by Shekelton," and the use of the name "Shekelton's aneurysm" as a synonym for dissecting aneurysm is not justifiable. Dr. Peacock, in the paper to which I have already referred, collected eighty instances in which the affection appeared in well-marked form, including five cases published by Shekelton,[4] R. W. Smith,[5] Kirkpatrick,[6] Lees,[7] and MacDonnell[8] respectively, in the *Dublin Journal*. An interesting specimen was exhibited by Mr. Conolly Norman at the Pathological Section of the Academy a few months ago.

In the earlier published cases of dissecting aneurysm it was supposed that the separation of the coats of the artery took place between the middle and external tunic; but modern pathologists agree that the blood almost invariably makes its way between the laminæ of the middle coat, so that the outer wall of the aneurysm is formed of the outer strata of media together with the adventitia. In the vast majority of cases the rupture of the inner tunics is due to their excessive lacerability—the result of atheromatous degeneration. Indeed, out of 60 of Peacock's cases the arteries were found healthy in only two instances. Ziegler[9] suggests that in the rare absence of morbid changes in the coats of the vessels, traumatic injury to, or defective development of, the vessel-wall is the primary cause of the lesion, and Walshe[10] mentions two cases in which dissection of the aortic coats on a limited scale had been abruptly effected as the result of railway concussion. On the other hand, Rokitansky[11] supposes that in some cases a morbid condition of the external coat deprives the inner coats of support and so predisposes to their rupture.

Dissecting aneurysm is practically confined to the aorta and its large branches, although Ziegler[12] states—on what authority I do not know—that the small arteries of the brain are a usual seat of the affection. The internal rupture is usually situated at the origin of the aorta or in the ascending aorta—it was so in 55 out of 73 of Peacock's cases—but it has been found as low as the end of the abdominal aorta, as happened in Shekelton's cases. The direction of the internal rupture is generally transverse when it is near the aortic valves, whilst it is more frequently vertical at the beginning of the descending aorta. Ordinarily the arterial coats are torn asunder over from one-half to two-thirds of the circumference of the aorta, although the separation of the tunics occasionally extends completely around the vessel. The longitudinal extent of the separation of the tunics varies considerably; as a rule the aneurysm is limited to the ascending aorta, but it is occasionally found to extend beyond the iliac arteries. In my case the separation of the coats begins at the arch and ends in the left femoral, and in a very remarkable case recorded by Tessier[13] the separation extended from the commencement of the ascending aorta to the left popliteal artery. The dissection not unfrequently is carried along the primary branches of the aorta. For instance, in MacDonnell's and Tessier's cases it extended through the innominate artery and its branches to the internal carotid; in another case[14] it followed the course of the coronary arteries; in Laennec's case[15] it passed along the cœliac artery and in my case into the right renal artery. Some of the intercostal and lumbar arteries are frequently found to be cut across by the stream of blood, "so that a probe introduced into the aortic orifice of one of those little branches passes directly into the aneurysmal canal and traverses this before entering the artery itself, which thus appears to arise directly from the aneursym."[16]

In cases which have ended fatally within a short time there has been only a single opening leading from the aorta into the arterial coats, death having been usually due to the subsequent giving way of the external wall of the sac. This is the common form, comprising 73 out of Peacock's 80 cases; my case is also an instance of it. On the other hand, when life is prolonged for any considerable time the blood is found to have forced its way from the sub-adventitious sac back again to the blood-stream at some point farther on in the course of the vessel. In such chronic cases—of which Shekelton's and Fagge's cases were examples—the new blood-channel acquires an endothelial lining. The disease is specially common in persons of advanced age, and though it probably occurs more frequently in men than in women there is not the excessive preponderance in males which is the rule in ordinary aneurysms. Indeed, some writers say that it is more common in women. The case which I now relate, and the specimen which I exhibited, typically exemplify the symptoms and pathology of the early stage of the fully formed dissecting aneurysm.

CASE 1.—A man, aged sixty-five years, was admitted to the Whitworth Hospital under my care on Jan. 13th, 1898, complaining of severe pain in his back and of loss of power in his legs. On the morning of his admission to hospital he was on a ladder engaged in papering a room when he was suddenly seized with a violent pain in the lower part of his back and in his left hip. The pain appeared to start from his lumbar region and to shoot up into his chest and down to his left thigh. It was so intense that (to use his own expression) he "bellowed with agony." He felt faint but did not lose consciousness and he was able to walk across the room with difficulty to a chair. Within a quarter of an hour his lower extremities were completely paralysed and his left leg was anæsthetic. He was removed to hospital in a few hours. Beyond the fact that he was a painter there was nothing noteworthy in his personal history and he came of a healthy family. On admission to hospital he was found to be a well-nourished, grey-haired old man, rather anæmic. He was unable to walk but he could move his legs slightly. He still suffered from severe pain in his back, but he had already recovered sensation in his left leg. Everything he ate or drank was vomited. His arteries, in which there was visible pulsation, were atheromatous and his pulse was high-tensioned. The heart was hypertrophied; no murmurs could be detected, but the aortic second sound was accentuated. He was carefully examined for aneurysm with a negative result. Pulsation could be felt in both of his femoral arteries. There was marked arcus senilis and his gums showed a "lead line." His urine was feebly alkaline, of specific gravity 1014, clear, contained 0·2 per cent. albumin, and a few hyaline and granular casts; neither sugar nor blood was present; the quantity of urine passed was about

the average amount. He had control over the sphincters of the bladder and rectum. The knee-jerks and plantar reflexes were lost. The pain in his back ceased after twelve hours and next day he felt much better and he was able to move his legs freely. On the following morning he was able to walk a few steps and he expressed himself as feeling almost quite well. At this period I showed him to the hospital class and I diagnosed the case as plumbism and chronic interstitial nephritis, with the usual cardio-vascular changes. I pointed out that the history of the attack clearly indicated some vascular lesion of the spinal cord, and the sudden onset, wide diffusion, and intensity of the pain, together with the transient duration of the paraplegia, appeared to justify the further diagnosis of spinal meningeal hæmorrhage. The patient was apparently well about 4 o'clock in the afternoon, when he took a drink of milk. Five minutes afterwards the nurse found him dead in his bed. His death occurred about fifty-two hours subsequent to the onset of the symptoms.

The post-mortem examination, which was made within 24 hours of his death, showed the right pleural cavity to be filled with blood. The pericardium contained a little clear serous fluid. The heart was rather large, there being hypertrophy of the left ventricle. The arch and upper part of the descending aorta was distended and formed a tumour-like mass, from which the blood had escaped into the right pleura. On opening the aorta its inner aspect was covered with atheromatous plaques, and a dissecting aneurysm extended from the arch at the level of the innominate artery and terminated in the left femoral artery about an inch below Poupart's ligament. A large mass of freshly-coagulated blood was effused between the tunics at the level of the arch and in the upper portion of the descending thoracic aorta, and here the separation of the tunics took place around nearly the whole circumference of the vessel wall. From the abdominal aorta through the left common iliac, external iliac, and femoral artery the coats of the vessels were separated by a thin layer of coagulum, but no palpable thickening of the arteries was so produced. In the lower part of the aneurysm the dissection of the arterial coats did not extend much more than halfway around the circumference of the vessels.

The microscopic sections, which I exhibited, were from the left common iliac artery, and they showed that the blood was effused in the substance of the middle tunic of the artery, so that the external wall of the aneurysmal canal was composed of the outer muscular strata of the media together with the adventitia. The dissection was carried along the coats of the right renal artery, the lumen of which was also occluded by a thrombus. The lumbar arteries were cut across and their orifices likewise contained thrombi. A large coagulum was adherent to the posterior wall of the aorta at the level of the renal and lumbar arteries. The external rupture of the aneurysm was situated about the middle of the thoracic aorta on its posterior aspect. The rupture was an ill-defined, oblique slit, about half an inch long, from which the blood had forced its way through the connective tissue into the right pleura. I have not been able to satisfy myself as to the position of the internal rupture. It might have occurred two or three inches from the termination of the abdominal aorta, for the atheromatous changes were most intense in that position, or possibly it took place at the origin of one of the primary branches of the aorta. Both kidneys were cirrhotic, the right one being, in addition, cystic and extremely engorged with blood. Microscopic sections of this kidney (prepared by Dr. Dargan in Dr. McWeeney's laboratory) showed that it was in a condition of universal hæmorrhagic infarction. There was no hæmorrhage in the spinal cord or its membranes. In the light of the necropsy it was not difficult to account for the symptoms of this case. As predisposing causes of dissecting aneurysm my patient had extensive atheroma of the inner coats of his aorta, which were consequently unduly lacerable and in addition he had hypertrophy of the left ventricle with high arterial tension. The intense pain at onset of the symptoms was due to the primary rupture and separation of the coats of the aorta by the blood; the paraplegia was caused by the interference with the arterial supply to the lumbar enlargement of the cord, partly from thrombosis, and partly from rupture of the lumbar arteries; the sudden death ensued on the rupture of the external wall of the aneurysm and the consequent escape of blood into the right pleura. It is rather remarkable that his urine contained no blood and that the amount passed was not noticeably diminished, for the right kidney was engorged with blood and its secretion must have been completely arrested.

Other cases of dissecting aneurysm have been recorded in which a remarkable series of symptoms was due to arrest of vascular supply to the brain, kidneys, or cord. Tessier's[17] patient died with the symptoms of apoplexy and a dissecting aneurysm was found extending from the arch of the aorta along the innominate artery and its branches to the internal carotid. Todd's[18] case was characterised by hemiplegia and transient suppression of urine, and the post-mortem examination showed softening of the brain due to obstruction in the carotids, and it is probable that there was also obstruction in the renal arteries. Sainet[19] records a case in which the patient became rapidly paraplegic. Latham and Swaine's[20] case was diagnosed during life. The patient was suddenly seized with "agonising" pain in his chest followed by paraplegia. In Dickenson's[21] case a policeman, after seven hours on his beat, was seized with loss of power over his lower extremities, followed by pain and collapse. Death took place within twenty-four hours. Where the symptoms are liable to such variations it is evident that the diagnosis of dissecting aneurysm must always be difficult and uncertain.

In reference to treatment Walshe[22] somewhat cynically remarks: "Were the practitioner fortunate enough to divine the occurrence of acute separation of the coats of the aorta it does not appear that in the present state of our knowledge the management of the case would be materially improved by his sagacity. Did he fail to diagnose the occurrence his aim would be to restore the patient from the first shock of the accident, control excited arterial action, and relieve symptoms as they arose. And it does not appear that art could do more than this were the anatomical nature of the affection understood from the first."

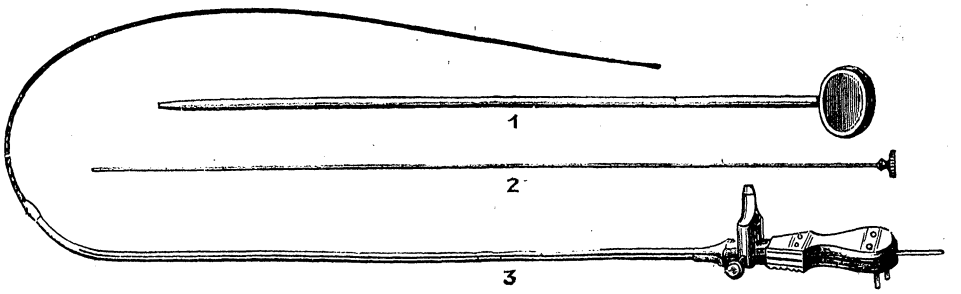
ON A MODE OF STRETCHING SOME URETHRAL STRICTURES.

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL.

IN some remarks on urethral stricture previously published[1] I have referred more particularly to its treatment by dilatation and by certain forms of urethrotomy or section. I have also described some instruments I usually employ with these processes. In an obstructive disease which presents so much structural variety cases are occasionally met with where, either from the urgency of the symptoms or the nature of the stricture, it will be found impossible to utilise these methods and modifications of them may be substituted with advantage.



The rarer cases of advanced stricture to which I am now referring usually owe their urgency to being complicated with some degree of retention of urine which also calls for surgical aid. A man of middle age, I will say, has been suffering from a neglected stricture for some months or years. Eventually he is either suddenly seized with inability to pass urine at all or he becomes seriously inconvenienced by the increased tension of a never emptied bladder. Let it be assumed that the stricture is so hard, contracted, or tortuous as to resist hot baths, opium, and catheterism with all forms of flexible instruments, and access to the bladder can only be effected by a fine metallic catheter. Possibly this even may require the aid of an anæsthetic. If such a catheter is tied in it not unfrequently slips out during the night and all the trouble of replacing it or substituting a somewhat larger one has to be repeated and not always with success. Even if it is retained it may not be possible to substitute a larger one and thus the progress of the case in giving increased relief to the patient is either hindered or proves impossible. Nor is the retention of a fine catheter, such as No. 1, 2, or 3, in a septic bladder to be desired, even though some relief to tension is afforded, any more than a drainage tube which will not drain is of service with a putrid abscess. Unless the relief is sufficient in either case sepsis is sure to follow if it has not already commenced. With a small catheter such as those I have referred to it is impossible to wash out and disinfect the bladder, and puncture or any forms of cystotomy or urethrotomy are not always advisable under these circumstances. It is in cases of this type, when the surgeon has succeeded in passing a small metallic catheter through a tight and difficult stricture into a more or less distended bladder, that the inability to expand the instrument at the same time, and so to stretch the stricture before withdrawing it, is not unfrequently experienced. With this object in view I described some years ago an instrument constructed on the lines of a Holt's dilator which appeared to meet the difficulty, and I have since continued to use it with advantage. It is provided with a pilot guide as well as with a screw top in case the former proves useless. It contains a fine test catheter on which the dilators run. It is fitted with a series of seven rods by which dilatation may be carried from a No. 3 to a No. 12 (English gauge), and the introduction of the latter is controlled by a spiral spring which consolidates the instrument and makes it act as one piece. On the dilator being passed, as an equivalent to a No. 3 catheter, the stylet is withdrawn and the correct position of the instrument is judged of by its transmitting urine and from its position relative to the rectum. Then the introduction of the dilating rods in accordance with their number and size is

[1] THE LANCET, April 23rd and June 11th, 1898.

Digitized by Google

proceeded with whilst the anæsthetic is continued. This is to be done deliberately so as to stretch and not to lacerate the stricture, the process usually lasting, according to the rigidity of the contraction, from about ten to twenty minutes. When the largest rod is reached the fully distended instrument, now representing No. 12 in calibre, is quietly withdrawn and the urine that remains is drawn off by a full-sized silver catheter, which may be passed easily. The bladder is then washed out and disinfected and a soft catheter is tied in and retained for forty-eight hours or so. As the process is one of stretching alone rigors or fever rarely follow.

The subsequent management of the case merely consists in instructing the patient how and when to pass a bougie for himself and so to endeavour to permanently maintain the normal dimensions of his urethra. It is hardly necessary to illustrate the kind of case to which this treatment is applicable, as it will readily occur to those who have had any practical experience of them. In proceeding to adopt it the only drawback which is likely to happen is the case proving, on trial with an anæsthetic, to be an impassable stricture. Under such circumstances Wheelhouse's perineal operation would probably be selected as the alternative. Where, however, the dilator can be passed in the manner I have endeavoured to describe both patient and practitioner will be none the worse for knowing that the retention of urine has been relieved in such a way as will permit the introduction of a full-sized catheter into the bladder.

Lower Berkeley-street, W.

ON A MODIFICATION OF MR. COXONS' METHOD OF PROLONGING NITROUS OXIDE ANÆSTHESIA DURING DENTAL OPERATIONS—

NAMELY, BY MEANS OF A MOUTH TUBE AND CLOSURE OF THE NARES.

BY W. J. McCARDIE, B.A., M.B., B.C. CANTAB.,
ANÆSTHETIST TO THE GENERAL HOSPITAL AND TO THE DENTAL HOSPITAL, BIRMINGHAM.

THE recent endeavours to prolong nitrous oxide anæsthesia for the purposes of dental surgery by means of a mouth-tube, nasal catheter, or nose-piece have all tended to supply a very distinct need—viz., an anæsthesia longer than the usual one of about half a minute and perhaps not so long a one as that obtained so easily and safely by the administration of nitrous oxide followed by ether.

I believe that for all lengthy or severe dental operations, especially in cases where numerous teeth or many bad stumps have to be extracted or in cases in which the patient is very young or old or in feeble health and the operation is of more than ordinary severity, three or four full breaths of nitrous oxide followed by a short inhalation of ether is by far the best method of anæsthetisation, for the shock during and after operation is in these cases less than that occurring during or after the administration of gas. The delayed return of consciousness is often of distinct advantage to both the operator and the patient, and the anæsthetist is left with a freer hand to help the dentist, who for his part can with confidence reckon on having plenty of time and is not embarrassed perhaps with anæsthetic appliances.

Last winter, at a meeting of the Society of Anæsthetists, Mr. Coxon, L.D.S., of Wisbech, demonstrated his apparatus for the prolongation of nitrous oxide anæsthesia. It consisted essentially of a mouth-tube made of hard metal with a diameter of about half an inch, at one end nearly half curved and at the other made to fit in the place of the face-piece and stopcock of an ordinary gas apparatus. Mr. Coxon warmed the gas before use by passing it through a metal coil immersed in hot water and interposed between the gas cylinders and the gas bag. In administration the patient was in the usual way put fully under the influence of nitrous oxide, then the face-piece was rapidly replaced by the oral tube, which was inserted into the mouth in such a way that it rested on the back of the tongue, and the free end was in the pharynx pointing towards the side of that cavity. The anæsthetist had of course to keep the tube out of the way of the operator and to arrange that a copious stream of gas was delivered from a fully-distended gas bag and passed on to the pharynx beyond the region involved in the operation and also beyond any collection of blood in the mouth. Mr. Coxon stated that he had often used this method of his devising and had had exceedingly good results from it.

I was much interested in his demonstration and had a metal tube like his made for me, but not regarding the warming of the gas as of importance in short operations at any rate, even if it be so in long operations, which I think doubtful, I made trial of the method without using any heating apparatus on many patients at the Birmingham Dental Hospital. As I preferred to keep the fullest command of the head and jaws and had to manipulate the gag I asked Mr. Thompson Madin, L.D.S., surgeon to the hospital, to kindly insert the mouth-tube for me and take charge of the gas-bag while I controlled the anæsthesia by means of the gas-supply.

The first few cases of trial were not very successful, but we soon became more proficient, and after a little time the great difficulty—that of inserting the tube to the back of the mouth and at the same time keeping it out of the way of the operator, especially in cases where the mouth was small—was dexterously overcome. We found that a central gag—e.g., Brunton's—wherever it could be used was the best. The gas-bag had generally to be kept fully distended and in the case of strong patients even had to be compressed between the arm and side of the body to increase the delivery pressure. It will be seen that a good deal of gas had to be used, for it escaped both by the mouth and the nose. I constantly for some months used this method in cases which needed a longer administration than usual and had a large measure of success. In many instances the duration of the anæsthesia was only determined by the conclusion of the operation. As the extractions were performed by students much longer periods of anæsthesia than usual were sometimes necessary and times of from one to four minutes were recorded without any untoward present or after-effects being noticed except that giddiness lasted perhaps a little time longer than after the ordinary sitting. I judged of the degree of anæsthesia chiefly by the colour of the face, managing the supply of gas so that the patient's lips were kept slightly cyanosed and the breathing rather snoring in character. After the above method had been in use for a few months Mr. Madin ingeniously thought of the modification of closing the nasal passages in order to prevent the escape of nitrous oxide and to limit air entry. After closing the nose by manual pressure he proposed to pass the tube just inside the mouth at a corner and to keep it full of gas by using only a moderate pressure. He himself made trial of this plan with perfect success. As the closure of the nostrils by digital compression

Digitized by Google

allows only one hand to be free I had a small nasal clamp made which might be fixed immediately after removal of the face-piece.

This modification of Mr. Coxon's method has been even more successful in our hands than the original plan, and with Mr. Madin's kind help I demonstrated its application at the annual meeting of the Central Counties Branch of the British Dental Association, held at Worcester on July 9th, Mr. Surman of that city being good enough to find a suitable patient. This demonstration very well illustrated the prolongation of anæsthesia by this modified method. The subject, a woman of ordinary type and about thirty years of age, needed the removal of eleven teeth, nine in the upper and two in the lower jaw, including many stumps. After the insertion of a Brunton's gag between the jaws and in the middle line full anæsthesia was induced in the ordinary way by means of Hewitt's apparatus, and when the face-piece was removed the oral tube was quickly substituted for it and inserted by Mr. Madin into the corner of the mouth away from the operator, while I manually compressed the nares and allowed a stream of nitrous oxide to pass from a gas-bag kept moderately distended through the tube, endeavouring to merely keep the mouth full of the gas. An uninterrupted and perfect anæsthesia was obtained, characterised by slight cyanosis of the face and lips and by quietly snoring breathing. The mouth tube was so well manipulated that it did not at all embarrass Mr. Malcolm Knott, the dental surgeon, who was operating with deliberation, especially in the extraction of the last few teeth. The duration of operation was two and a half minutes, and after it had been finished the anæsthesia was prolonged for another half-minute for the purpose of further demonstrating the ease of maintaining it as long as might be necessary. During the latter part of the operation the Brunton's gag was changed for that of Mason. The operator would have done very well indeed to have extracted all the teeth in two ordinary sittings for gas.

This was a most successful case for a demonstration, the patient being well under throughout without movement of any kind, slightly cyanosed as regards colour, her breathing being easy and rather snoring in character. The operator was very pleased with the result. Recovery of the patient was extremely rapid and not marked by any untoward symptom—indeed, was exactly like that after the usual half-minute anæsthesia. The quantity of nitrous oxide used was about 48 gallons and supposing that 8 gallons (which is perhaps a little above the average for an adult) were used in inducing full narcosis, then only 8 gallons were used for each extra half-minute of anæsthesia, a quantity which is considerably less than that used in the same time by Mr. Coxon's original method. For, supposing the nasal passages to remain open and manipulation to be going on in the mouth, there is a tendency for the patient, even in the case of mouth-breathers, to breathe wholly through the nose and the inhaled nitrous oxide is very largely diluted with air in the pharynx, while during expiration and the pause between expiration and the following inspiration there is free vent through the nares for the escape of the gas as well as of air. If the nostrils be blocked much gas is obviously saved, and as possibly some reflex hindrance (induced by the oral interference) to free respiration still exists, the breathing is for a short time at any rate quieter and less frequent, and if the mouth be simply kept full of nitrous oxide it can well be effected that enough gas is inhaled to maintain full anæsthesia, while it is diluted with a not too large quantity of air.

In suitable cases the duration of the anæsthesia may be determined only by the conclusion of operative interference. Where it is possible digital has an advantage over instrumental compression of the nares, in that it gives one more command over the head and can be applied very easily at any period of the anæsthesia, while it is sometimes difficult to quickly apply or reapply a clamp with one hand. One or two chief points for guidance in the use of this modified method have already been indicated, but the last and not the least remains to be noted and concerns the question of an assistant to the anæsthetist. In any dental operation where more than a few teeth have to be extracted under gas in the ordinary way a dexterous speed is necessary on the part of the operator, and it is often advisable for him to have an assistant who shall help him in the matter of sponging, handing instruments, &c., but if this method of prolonging anæsthesia be adopted the operator can take his time and do his own sponging and the assistant (if only three persons besides the patient be present) may help the anæsthetist, for it is a very great advantage to have some one to change the face-piece for the mouth-tube and if skilled to insert and manage the tube while the administrator concerns himself with more serious matters, such as the condition of the patient and degree of anæsthesia, the command of the head and jaws, the manipulation of the gag, the closure of the nares, the gas-supply, and watches that no blood or foreign bodies be allowed to remain in the mouth. The tube I use has an internal diameter of about ¼ in., is made to fit my Hewitt's gas apparatus, and can be carried in the pocket. The advantages of the method are obvious. It is extremely simple and adaptable, needing no cumbrous, complicated, or novel apparatus, and can be effectively applied to probably the large majority of patients who can take gas in the usual way, doing away with the need for many a second sitting for extraction, saving time and trouble to both patient, anæsthetist, and operator, and also perhaps sparing the patient the mental discomfort of anticipating a second administration. I use the modified method in most cases (at the Dental Hospital) requiring a longer anæsthesia than usual.

The disadvantage of the method is that it needs some practice on the part of the anæsthetist and also on the part of the assistant, if one be present, to successfully keep the tube out of the way of the operator. I do not think, as I said earlier, that for really long or severe dental operations the original method of Mr. Coxon or this modified one will or ought to replace the administration of gas and ether, but both should hold a place midway between the ordinary gas inhalation on the one hand and the use of gas followed by ether on the other.

Birmingham.

THE DIAGNOSIS OF HYSTERO-EPILEPSY FROM STATUS EPILEPTICUS.

BY WILFRED R. KINGDON, B.S., M.B. DURH.,

RESIDENT MEDICAL OFFICER OF THE TICEHURST ASYLUM, SUSSEX; LATE ASSISTANT MEDICAL OFFICER TO THE MALE SIDE OF THE BIRMINGHAM CITY ASYLUM.

WE are indebted to French writers, and especially to Professor Charcot, for the more important descriptions of hystero-epilepsy; indeed, the condition appears to be much more frequently found on the continent than in England. When met with in the Anglo-Saxon race this disease seems to be not infrequently of such a type as to be easily mistaken for status epilepticus by those who are unaccustomed to see epilepsy in its severer forms, and for this reason I venture to think that some short account of two cases which it has been my fortune to see during the past two years will not be altogether without interest.

CASE 1.—About sixteen months ago I saw a young woman, seventeen years of age, who was supposed to suffer from epilepsy and who had had that morning what was said to be "status." She was of a highly neurotic family, two or three relatives were described as "hysterical," and, if I remember rightly, a grandfather had attempted his life and ended his days in a lunatic asylum. The patient had been what some would call "over-educated," but which I would prefer to describe as improperly educated—in fact, "crammed." I elicited after some difficulty the following facts concerning the "status" which was said to have taken place. She had been melancholy for a day or two and that morning had complained of pain in the left iliac region and great tenderness when the part was palpated. A feeling of suffocation ushered in the actual attack, followed by fixation of the pupils and then a well-marked tonic stage. The clonic stage was less marked and gradually passed into a condition of violent gesticulations combined with attempts to strike her head and injure those around her. This would continue until apparently she was thoroughly exhausted and then she would gradually become quiet and pass into another convulsion. The patient had been taking at one time and another bromides and the *dragées antinerveuses de gélineau*, but without, it seemed, much result.

The fact of the tongue not having been bitten, the kind of movements (as though with a purpose or object), the struggling with those who were restraining her, the length of each fit, the "something rising in her throat" which she described, and, last of all, the absence of any good result from

Digitized by Google

the treatment of her previous condition led me to believe this to be a case of hystero-epilepsy.

CASE 2.—The patient was a neurotic-looking woman, twenty-two years of age, recently married, who had been weakened by an attack of influenza a short time before. During her school days she had had two or three "fits" of some kind, this being, so far as I could gather, when she was about the age of puberty. It was after a hard day's sight-seeing at Versailles—a lot of the time having been devoted to looking at pictures—that the attack came on. She had gone to her room thoroughly worn out to get ready for dinner when she felt tremulous and very nervous, even going so far as to say that she had a feeling that "something dreadful" was going to happen. She sat down to rest a few moments, but had not been on the chair more than two or three minutes when with a shriek she fell on the floor and was seen to be convulsed. When I saw the patient she had had one fit and another was just commencing. The tonic stage was well marked, the back and legs were extremely rigid, and the former was slightly arched. The pupils were dilated and fixed. This lasted for about 25 seconds and then the face began to twitch, the eyelids began to open and shut rapidly, and the to-and-fro movements of the arms and legs quickly followed. Frothy saliva escaped from the mouth, but was unmixed with blood and the face was but slightly livid. For about half a minute these movements were quite epileptic in character, just to-and-fro movements without aim or object, but gradually they began to lose this characteristic, she began to strike her head violently on the pillow as though she wished to injure herself, and she kicked out at us and attempted to bite our hands. She would pause in the midst of all this and remain quite still with her head a little on one side, as though listening (evidently aural hallucinations were present) and then become violent again. The duration of this stage varied from 15 to 25 minutes and then the patient would become quiet and remain in a semi-conscious exhausted condition for a few moments, when the cycle would begin again. All the fits were much alike; the only thing of note was that on one occasion, and one only, was there marked opisthotonos. I administered a hypodermic injection of hyoscine hydrobromate ($\frac{1}{75}$ gr.), which caused the fits to cease and produced five hours' sleep. On awaking the patient was very emotional and far from well, but there was no return of the fits; her tongue had not been bitten and she spoke of having been "choked with something"—evidently "globus."

Hyoscine, we know, is most useful in cases of status epilepticus and in the convulsions associated with general paralysis of the insane; it appears to be of service also in this condition of hystero-epilepsy, and certainly it is much less tedious than the old chloroform method.

Ticehurst.

A CASE OF PACHYDERMIA (VIRCHOW).

BY E. M. LIGHT, M.A., M.B. CANTAB.

THE patient, a man, aged fifty-one years, consulted me in 1895 for a pain on the left side of the throat on swallowing his saliva—nothing else and no pain at any other time. The present symptom had lasted for three months and he gave a history of the same trouble two years previously. He had never noticed the presence of blood in his saliva. He was especially anxious to have the existing condition of his throat cleared up as his father and an uncle had died from cancer. For the last twenty-five years he had suffered from asthma which was worse in autumn, and on inquiry I found that his mother had suffered equally from the same complaint. He weighed 10st. 9lb. and had not lost flesh. On examination with the laryngoscope there was to be seen a distinct ulceration, owing to the break-down of the thickened parts, on the processus vocalis of the left vocal cord, completely corresponding to where he felt the pain and inconvenience. The neighbourhood of the spot was considerably congested. I advised him independently to see Sir Felix Semon, which he did, by whose kindness I received a letter verifying the above condition of the left vocal cord, enclosing a sketch, and stating the case to be one of pachydermia (Virchow). How the patient came by this rather rare affection it was impossible to say, as he lived quietly in the country, was not a great talker, and was moderate in what he drank as in everything else. No local treatment was advised except applications of cold externally (cold compresses at night) and sucking of ice, in order not to irritate still further the part. The importance of resting the voice and of the avoidance of irritants (dust, stale tobacco smoke, hot and peppered food and drinks, &c.) was impressed upon him. Internally, iodide of potassium in 5-grain doses three times a day was prescribed for some time. In about three weeks he wrote to say that his throat was better and the irritation less, but that the medicine gave headache, so the dose was reduced to twice daily. Three weeks later he again wrote to say that he had no pain in the throat and felt quite well. He was advised to continue the iodide of potassium and after another period of six weeks he was again seen by Sir Felix Semon and myself and was pronounced cured. He is alive and well at the present time and has had no return of the affection.

This case is interesting from many points of view. A certain number of authorities, Schrötter among them, deny that a simple chronic laryngitis is ever capable of causing ulceration of the mucous membrane, its presence denoting the existence of specific lesions, tuberculous or syphilitic, and that when one sees lesions apparently ulcerative it is in reality a desquamated mass of epithelial cells or of mucus, without loss of subjacent substance. On the contrary, Störk, Schnitzler, and Heryng[1] consider the existence of "catarrhal" ulcerations as an absolutely undeniable fact. Virchow has confirmed this opinion, his term "erosive" ulcerations denoting a number of simple erosions, as there is never extensive and deep loss of substance. Again, the clearness of outline of the ulcerations, the intense redness of the limiting mucous membrane, the raised appearance of the surface, the seat of the erosions on the internal surface of the cords, the absence of any previous localised infiltration, with the existence of an interarytenoid desquamation with irregular outlines, lead one to consider that the condition is not of bacillary origin, and the spontaneous cure of the erosions confirms this view.

According to Virchow pachydermia is only a chronic inflammation of the mucous membrane of the larynx, a lesion resulting either from a simple catarrh, tubercle, syphilis, or early cancer. The "diffuse" form of pachydermia is especially associated with abuse of alcohol or tobacco, the excessive use of the voice in the open air, or exposure to the inhalation of various forms of dust, while the nodular form is more closely associated with children, women of middle age employed as teachers, actresses, singers, or girls who have been badly taught to sing, and rarely with men.

The nature of the laryngeal affection indicated by the aspect, disposition, and seat of the lesions; the course of events, age, sex, and mode of life of the patient; and the state of the nasal fossæ and pharynx, &c., help to fix a diagnosis. The affection, though chronic and progressive and often rebellious to treatment, is curable, but often enough when one side gets better the other becomes affected.

Wilton-place, S.W.

NOTE ON A MODIFICATION OF THE WEIGERT-PAL METHOD FOR PARAFFIN SECTIONS.

BY E. E. LASLETT, M.B. VICT., B.SC. LOND.,
HOUSE SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

So far as I am aware no mode of procedure has yet been published by which the Weigert staining method for nervous tissues can be applied to paraffin sections. For some time attempts were made to apply the method which is known in Schäfer's Histology as the Weigert-Pal process to paraffin sections by first fixing them on a slide and, after removal of the paraffin in the usual way, treating with Marchi's solution, followed by the acetic acid hæmatoxylin. This method was found to be unsatisfactory, as, although the nerve fibres were marked out in a more or less definite way, it was seen on close examination that they did not really stain in "ring fashion" at all. In sections stained

[1] Heryng: Revue de Laryngologie, 1er Mai, 1885. Schnitzler: Congrès International de Laryngologie de Paris, 1889.

Digitized by Google

by the Weigert method it is the medullary sheath which should be picked out, appearing in cross section as a black ring, whereas in the sections treated as above it was practically the axis cylinder only which retained the hæmatoxylin after differentiation.

The following method was next tried and it has proved an efficient and trustworthy one. The material—spinal cord, medulla, or other tissue—is hardened for about a fortnight in Müller's fluid and then cut into slices which should not be more than about 2 mm. in thickness. These are placed in Marchi's fluid for a week, washed, and embedded in paraffin in the usual way. Thin sections are cut, fixed on the slide by the warm water method, and then after removal of the paraffin placed in the acetic acid hæmatoxylin overnight, preferably in a warm oven, the heat materially hastening the process of staining. After washing they may be passed into a saturated solution of sodium or lithium carbonate, by which the colour is changed to a bluish black. They are then differentiated by the Pal method, in which process it is advisable to use weak solutions, watching the progress of the change carefully lest the sections, which are very thin, become too much decolourised.

The advantages of the above method are (1) that it is a combination of the Marchi and Weigert methods and is therefore applicable to pathological nervous tissues in all stages of alteration and (2) that it offers the advantages of paraffin over celloïdin as an embedding material, the chief one of which is the extreme thinness of section attainable. In thin sections stained as above the fine medullated fibres of the grey matter show a double contour quite plainly. Hence it should be easy to trace the course of degenerating fibres in the grey matter itself, the regular double contour being then broken up in the characteristic way into black staining droplets of myelin. Provided that the pieces placed in the Marchi's solution are not more than 2 mm. in thickness, sections of the human medulla may be quite successfully stained in this way. Professor Sherrington has very kindly examined my specimens, and he considers the method likely to prove a useful one.

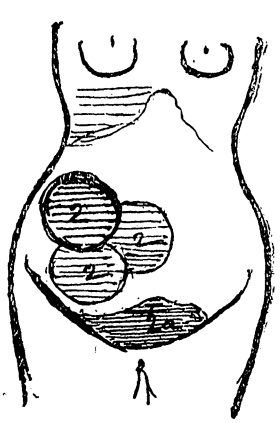
PREGNANCY SIMULATING PEDUNCULATED FIBROID.

BY E. PAGET THURSTAN, M.D., B.A. CANTAB., M.R.C.S. ENG.

I WAS asked on May 20th, 1898, to assist my friend Dr. J. A. Haynes of Perth, Western Australia, to examine a patient under chloroform to ascertain if she were pregnant. The patient, a married woman, who believed herself to be four months pregnant, had had a vaginal discharge with only intervals of a week or ten days ever since the supposed pregnancy began. She came seeking relief from severe pain in the back and in the groins, as well as to relieve her mind of a doubt as to whether she was pregnant or whether she had a tumour. She had milk in her breasts but had had no morning sickness. There were no signs of quickening nor could the fœtal heart or any placental bruit be heard. On palpation the abdomen was found to be enlarged and a tumour of irregular outline could be felt above the pubes. Vaginal examination showed the os high up, patulous, and apparently torn by previous labour. No presentation could be made out. Bimanually at first a round, hard mass (Fig. 1—1) could be felt on the tip of the finger much like a post-partum uterus, while behind it was an irregularly shaped mass (Fig. 1—1*a*). This mass could only be moved within very small limits, as from 1*a* (Fig. 1) to 2*a* (Fig. 2), but the round lump was very freely moveable. On the right side it rose well above the level of the umbilicus and almost merged into the liver dulness (Fig. 2). On the left side it had a lower range, as well as one more limited laterally. Both on the right and the left, however, it was plainly connected to the pelvis. Owing to the presumption of pregnancy no sound was used.



My diagnosis was pregnancy with pedunculated fibroid, but no operation was advisable unless the pain became unbearable or the hæmorrhage proved to be alarming. Dr. Haynes's view was that though pedunculated fibroid was probable there was a possibility that the whole tumour was uterine, as a case had occurred in New South Wales in which an operation had been performed on a supposed

FIG. 1.

1, The round, freely moveable mass. 1*a*, The irregularly-shaped, less freely moveable mass.

FIG. 2.

2, The mass marked 1 in Fig. 1 in its new position. 2*a*, The mass marked 1*a* in Fig. 1 in its new position.

tumour which had ultimately proved to be a uterus with a very elongated neck, a bicornual uterus with one horn extremely developed. Both of us were agreed that pregnancy was probable and that an operation was therefore not indicated.

On May 23rd—three days later—after violent hæmorrhage and severe pain the patient was suddenly delivered of a fœtus with membranes, placenta and all in one mass. The appearance of the afterbirth showed that there had been placenta prævia. The tumours disappeared at once.

This was probably a case of elongated neck of uterus with very thin walls allowing the fœtal head to be felt through the abdominal wall as a floating tumour. It shows the need of caution in the diagnosis of abdominal tumours.

Perth, Western Australia.

DIPHTHERIA OF THROAT, NARES, CONJUNCTIVÆ, AND URETHRA.

BY W. HERBERT GREGORY, M.D., C.M. EDIN.

ON June 6th, 1898, I was summoned to attend a man aged twenty years. The history was that he had felt "shivery" for a day or two previously and had some difficulty in swallowing. His fauces, tonsils, and uvula were deeply congested but not patchy, and the cervical glands were greatly swollen. I diagnosed the case as one of commencing diphtheria and ordered a lotion of perchloride of mercury (1 in 2000) to be sprayed frequently and another lotion of 1 in 500 to swab the throat three or four times daily. I also gave 20 minims of tincture of perchloride of iron and 1 grain of sulphate of quinine every three hours. Strong soups, milk, and alcohol were also given. On the following day (June 7th) his temperature had risen to 101·8° F. There was a greyish-white membrane on the tonsils and uvula and an acrid discharge from the nares indicating extension to the nasal mucous membrane. There was also great swelling of the lower eyelids. On June 8th his temperature had risen to 103·8° and the membrane had spread over the soft palate. The discharge from the nares had increased, the eyelids were very swollen, and there was membrane on the palpebral conjunctivæ. There was also a patch on the anterior lip of the meatus urinarius causing difficulty in micturition. I had by this time received a supply of anti-diphtheritic serum from Messrs. Burroughs, Wellcome, and Co., and of this I injected 20 c.c. Improvement rapidly took place, but a similar dose had to be repeated on three occasions owing to rise of temperature. The case progressed

Digitized by Google

without a single drawback, the membrane quickly disappearing from all the situations mentioned. I feared greatly that the corneæ would be destroyed, but this fortunately did not take place and the eyes have quite recovered. About a fortnight ago I had the secretions from the mouth and throat examined by the Clinical Research Association and no Klebs-Löffler bacilli could be found. There has so far been no sign of post-diphtheritic paralysis and the patient is now at the seaside and in excellent health. A curious point is that he had diphtheria six years ago. I venture to quote this case because of the unusual number of mucous membranes simultaneously involved and to show the rapidly curative effect of the anti-diphtheritic serum in a case more than ordinarily virulent.

Beverley.

EXPULSION OF ENTIRE UTERINE CONTENTS AT THE SEVENTH MONTH.

By W. F. GARDENER, M.R.C.S. Eng., L.R.C.P. Lond.

THE patient was a married woman, aged thirty-five years, a multipara. At the time of her delivery she was in the last stage of pulmonary phthisis, unable to lie down at all and greatly emaciated. She was seen on the morning of the day of her confinement and had then no pains. During the afternoon she sent for the nurse whom she had engaged to attend her during her confinement as she "felt her pains coming on." The nurse found these to be slight and infrequent and left her with instructions to send again if they did not leave her. In the evening she sent for the nurse again, shortly after whose arrival the pains became suddenly strong, and with two or three violent straining efforts the child, contained in the membranes, with the placenta, was suddenly extruded into the bed. On my arrival I found the uterine contents left *in situ* as they had been born. I immediately ruptured the membranes, but there was no movement of the child, which had apparently been dead for some hours. The uterus was firmly contracted and there was no further hæmorrhage. Of this there had been a slight amount at the birth but none whatever previously. The patient died during the following night. If the uterine contents were absolutely untouched, as the nurse asserted, there was not placenta prævia, as, judging from the position on the bed, the placenta came last.

Sydenham, S.E.

PRIMARY MENSTRUATION AND FIRST PREGNANCY IN MIDDLE LIFE.

By J. F. WOLFE, M.B. Edin.

THE following case deserves to be recorded on account of the great rarity of similar phenomena. A married woman, aged forty-five years, menstruated for the first time about eighteen months ago. When about nineteen years of age she was treated for amenorrhœa at the Portsmouth Hospital for a period of three or four months, but never had the slightest symptom or sign of menstruation until when in her forty-third year she was seriously frightened by an idiot (a step-daughter living in the same house). Menstruation thereupon commenced on the same day and lasted two or three days, from which time up to the date of impregnation, she menstruated but a few times and not at all regularly. The labour, which came on at full term of pregnancy, was much shorter than might have been expected, lasting not more than thirteen hours; the presentation was left occipito-anterior; the pelvis was roomy; forceps were not required. There was apparently nothing unusual about the external genitals, the mammæ were fairly well developed, and milk came freely on the third day. The patient has had seven brothers and two sisters, all of whom died under five years of age. She herself (the youngest) never had any serious illness, but is rather anæmic and has suffered from frequent headaches (not periodically) which do not appear to have lessened in frequency or severity since menstruation started. She has been married eleven years, her husband is healthy and has been living with her all the time. He had seven children by his first wife, all of whom are alive and healthy with the exception of the one above mentioned. For permission to publish this case, which as far as I can ascertain is unique, I am indebted to Mr. H. P. Gaston of Southsea, for whom I attended the patient.

ROYAL FREE HOSPITAL.

A CASE OF EXTREME COLLAPSE TREATED ON THREE OCCASIONS BY THE INTRAVENOUS INJECTION OF SALINE SOLUTION.

(Under the care of Mr. BOYCE BARROW.)

THE treatment to be adopted in cases of severe shock depends mostly on the cause which has given rise to it and the use of intravenous injection of fluid is practically chiefly of value in those cases in which a large amount of blood has been lost. Although occasionally success followed the transfusion of blood and the intravenous injection of milk, yet the results of these methods of treatment were on the whole very unsatisfactory. Even the employment of defibrinated blood as recommended by Panum of Copenhagen in 1863 was no more successful, and the operation was generally followed by a rise of temperature, possibly due, as explained by some, to fibrin ferment which had been set free in the process of whipping. The use of saline injections into the veins has now entirely replaced all other forms of transfusion. Many complex mixtures of various salts are recommended, but they take time to prepare and there is no evidence that the results following their use are any better than may be obtained by employing a simple solution of common salt of the strength of 1 drachm to the pint. The more extensive present use of the intravenous injection of saline solutions is in great measure due to the advocacy of this method by Dr. William Hunter in 1889. For the notes of this case we are indebted to Mr. Reginald Hayes, late house surgeon.

A delicate boy, fourteen years of age, who was suffering from cleft palate, was admitted to the Royal Free Hospital in January, 1897, with sinuses of the hip which had troubled him for nearly two years and for which some half-dozen operations had been performed elsewhere. For six months he had worn a Thomas's splint and during the past four weeks abscesses had formed in and around his right groin for which he had been treated at the local infirmary. An examination of the hip made it evident that there was a considerable amount of disease and in a week's time he was anæsthetised with chloroform (which was soon changed for ether) with a view to a more thorough investigation of his condition being made. He lost a good deal of blood in consequence of the considerable amount of fibrous tissue in which some large vessels were embedded making it difficult to secure them rapidly. Extensive disease of the pelvis, great trochanter, and upper third of the femur was found, a good deal of carious bone being removed and the cavity being finally packed with bicyanide gauze. Towards the close of the operation the patient's pulse became so feeble that brandy and strychnine were injected subcutaneously and an enema of hot port wine was administered while he was in the theatre. On removal to the ward his legs and arms were enveloped in cotton wool and were bandaged from the extremities upwards; the foot of the bed was raised and the patient was surrounded with warm-water bottles. Nutrient enemata with brandy were ordered to be administered every three hours as vomiting was troublesome, but as his condition got gradually worse, the temperature falling to 96° F. and the pulse becoming feebler and of a running character and all ordinary methods having failed, at 10 P.M. (six hours after the operation) over two pints of normal saline solution at 100° were injected into the left median basilic vein. Marked improvement was apparent for a couple of hours, when the patient became unconscious, with pupils widely dilated, the pulse imperceptible at the wrist and Cheyne-Stokes breathing. He was now apparently moribund, so it was decided again to try transfusion. The right median basilic vein was found

Digitized by Google

with some difficulty and over three pints of the saline solution were injected. Towards the end of the injection of the third pint improvement was very obvious; he recovered consciousness and attempted to sit up in bed, smiling and mentioning that he "felt better." The radial pulse became perceptible and of fair volume. He shortly afterwards fell into a sleep which lasted for over five hours and though for several days his condition remained critical he eventually made a good recovery. In about five months time, after a couple of thorough examinations under anæsthetics had been made, Mr. Barrow decided that in consequence of the amount of disease in the pelvic and thigh bones, and taking into consideration the patient's general condition, amputation at the hip-joint would afford him the best chance for his life. This was performed by a modification of the Furneaux Jordan method. Some difficulty was experienced in securing the common femoral artery, which was partially embedded in fibrous tissue and firmly attached to the bone. At this point a good deal of blood was lost. Towards the end the pulse became weak and running and profuse perspiration occurred. On removal to bed the patient became more collapsed; the temperature fell to 95° and the pulse was 146 and grew more and more feeble till it was scarcely perceptible. All the ordinary treatment of shock was tried without any improvement and the patient appeared to be sinking rapidly. Accordingly about 8.30 P.M. two pints of saline solution were injected into the right median cephalic vein, with the result that the temperature gradually rose to normal, and though his condition gave cause for anxiety for several days the lad ultimately made a good recovery. After a few weeks in a convalescent home he returned in the following month, looking very well, in order to have his cleft palate operated on, which was done with a successful result.

Remarks by Mr. REGINALD HAYES.—The case is interesting as showing the striking manner in which this patient reacted to the transfusion with saline solution after failure of the ordinary lines of treatment; and the effect of the second injection after the first operation, when from a moribund condition he recovered sufficiently to smile and speak, attempting to sit up in bed, was very remarkable.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

TWO CASES OF DISEASE OF THE SPINAL CORD FOLLOWING PREGNANCY AND LABOUR.

(Under the care of Dr. J. B. BRADBURY.)

THOUGH there are not wanting arguments in favour of the presence in the blood of toxic substances during pregnancy, and though this theory would serve to explain readily some conditions, such as the nephritis of pregnancy, which are not susceptible otherwise of any easy explanation, yet it must be admitted that in the vast majority of pregnancies there is no evidence of any toxins. The two cases which follow are well worthy of being placed on record, for they are very suggestive of some causal connexion between the pregnancy and the lesion of the spinal cord, though it would be rash to say that one was certainly due to the other. For the notes of the cases we are indebted to Dr. Francis Villy, house physician, and Dr. Burton, late house physician.

CASE 1.—A married woman, aged forty-three years, was admitted into Addenbrooke's Hospital on Sept. 21st, 1896. There was no family history of nervous disease or history of syphilis. The patient had been the mother of eighteen children and had had two miscarriages. Her health had been good till seven years before admission, when she gave birth to a hydrocephalic child. Pain and weakness across the loins followed this event and lasted for nine months; in a year from the same date she lost the use of the right arm and leg suddenly, no loss of consciousness or other cerebral symptoms occurring. There was no facial paralysis or alteration of sensation. About ten months before admission she began to have severe sacral pain; in five months pain occurred in the left knee also, and from that time she began to lose power in the left leg. The sphincters were never affected. On admission the right arm was weak without alteration of sensation or wasting; the reflexes were lively. The left arm was not affected. Both lower limbs were partially paralysed without alteration of sensation, the right one being more advanced than the left, which was slightly wasted. The knee-jerk was much exaggerated and ankle clonus was well marked on the right side; the left leg was normal in these points. Both legs underwent spasms of rigidity at times. No cranial nerves were affected. Subsequently cramp-like pains occurred in both legs and ankle clonus developed on the left side. A feeling of constriction round the abdomen also occurred but did not amount to a definite girdle pain. Under physostigmine the subjective symptoms improved considerably, though the physical signs were still present at the date of the patient's discharge from the hospital (Nov. 15th, 1896).

CASE 2.—A married woman, aged thirty-seven years, was admitted to Addenbrooke's Hospital on Dec. 29th, 1897. There was no family history of nervous disease. She had never enjoyed good health, but there was no history of previous disease except the occurrence of an ulcer of the stomach eighteen years previously. She was the mother of ten children and dated her present illness from her last confinement seven months before admission. She had had sacral pain ever since that event and had never been able to walk properly subsequently, though there had previously been no such difficulty. For three months the legs had been numb, though there had been a deep aching pain throughout their extent for some time. On admission the cranial nerves and the arms were normal. The sensations of touch, temperature, and pain were diminished almost up to the umbilicus, though they were not abolished completely. The distribution of this altered sensation was not regular, tactile sensation being fairly well developed at a zone round each knee and in the feet. Loss of sensation of temperature was most marked. The plantar reflexes were normal, both knee-jerks were much exaggerated, and well-marked ankle clonus was present on each side. The muscular power of the legs was good, no reaction of degeneration being discovered. The patient stated that her legs had wasted slightly during her illness; they were constantly in a spastic condition. The symptoms became steadily worse in spite of treatment and the patient was discharged from the hospital on March 12th, 1898, in a distinctly less favourable condition than on her admission.

Remarks by Dr. VILLY.—The symptoms of lesion of the spinal cord were in each of the above cases so marked and followed so closely after labour that a relation of effect and cause between the two occurrences suggests itself very strongly. Such a relation does not seem to be improbable *a priori*, for it has long been recognised that pregnancy (apart from any septic change due to labour) is a not very uncommon cause of peripheral neuritis.[1] Moreover, there are many who believe that in normal pregnancy there is a general toxic state[2] and such a toxæmia is a recognised precursor of certain diseases of the central nervous system; for instance, syphilis, typhus fever, influenza and other similar diseases may precede lesions of the central nervous system. I can find very little recorded of the production of such diseases by pregnancy. Sir William Gowers[3] mentions that primary spastic paraplegia has in several cases succeeded prostration after childbirth or abortion, or has commenced during lactation, but he gives no further account of such cases. Turney[4] mentions a patient in whom anterior poliomyelitis followed about a month after labour. To prove that the nervous lesions in the two cases in question were actually caused by pregnancy or labour would be a very difficult matter, for not only would it be necessary for such a purpose to exclude the recognised antecedents of similar diseases, but it must also be shown that mere coincidence has not simulated cause and effect. Though much more extended observations than the present ones would be necessary to exclude this last possibility, yet the cases seem to be sufficiently striking to suggest more than coincidence, and it is hoped that this note may serve at least to draw attention to the subject. It will be noticed that in each of the above cases the period of onset followed a considerable time after labour, a course which is at least unusual in peripheral neuritis. In both instances the symptoms were chiefly those of lateral sclerosis, though plainly the lesion was not of the pure form of that disease.

Reviews and Notices of Books.

Diabetes Mellitus and its Treatment. By R. T. WILLIAMSON, M.D., M.R.C.P. Lond., Medical Registrar, Manchester Royal Infirmary. Edinburgh and London: Young J. Pentland. 1898. Pp. 417.

DIABETES mellitus is a disease upon which physicians delight to theorise; the literature on the subject is immense, and there is probably no condition on which more opposite opinions are held by scientific men. Dr. Williamson has succeeded in producing an excellent *résumé* of the various views held as to the pathology of the disease as well as in giving us a large amount of information as to the symptomatology and treatment of the complaint based upon his own experience. After an introductory chapter the author deals very fully with the many tests which have been introduced for the detection and estimation of grape sugar in the urine. He speaks highly of phenylhydrazin as a clinical test for sugar and describes a simplified method of applying it. The reagents, he says, do not readily decompose and the test is easily carried out and consequently is very suitable for clinical work. It is very sensitive—more sensitive than Fehling's test and the fermentation test—but it is not too sensitive and gives no reaction with normal urine. It is also of especial value as a *negative test*—that is to say, a urine which gives no reaction by this method may be declared quite free from sugar for practical purposes.

Chapter III. deals with physiological considerations and demonstrates that the author has given much careful consideration to every detail of his subject. In Chapter IV. Experimental Diabetes and Glycosuria are discussed, the author remarking that "the theories which have been put forward to explain diabetes mellitus are exceedingly numerous. ..... The riddle has not yet been solved and probably the day is far distant when a satisfactory answer will be given. Nevertheless, many important facts have been ascertained and experiments on animals have furnished much interesting information." Dr. Williamson again shows his capabilities of sifting the information he has obtained, rightly deciding to refer only to the more important results of experimental work in a book devoted mainly to the clinical side of the subject.

Extremely interesting is the chapter on the Etiology and Etiological Relations of Diabetes and we would especially draw the reader's attention to the remarks on the relation between diabetes mellitus and lesions of the pancreas. Dr. Williamson considers that it is very improbable that all the varied pancreatic changes which have been recorded in diabetes are the *result* of the disease; but, on the other hand, he believes that in *certain cases* diabetes is *directly due* to pancreatic disease. The symptomatology of the disease, the complications and pathological changes in connexion with the various systems, together with diabetic coma, occupy three long chapters and form a most excellent description of the clinical aspects of the disease given by one who has evidently exceptionally good powers of observation and has made the most of the opportunities he has had for observing patients suffering from diabetes mellitus. The chapter on Treatment will naturally receive great attention from the reader and may be the subject of some adverse criticism, but on the whole we certainly agree with the system adopted by Dr. Williamson. The chief objects to be arrived at are (1) to diminish the amount of sugar in the urine and blood, to diminish the amount of urine, and to relieve thirst. These points are appreciated by everybody, but often the medical man proceeds no further unless there are (2) various complications which require treatment. There is a third object, however, which is often neglected—namely, to increase the weight, or at least to maintain it (except in those mild cases in which the disease is accompanied by obesity) and to improve the general condition. Dietetic treatment naturally holds the first place and the author's remarks are most full and valuable. He emphasises Minkowski's division into the mild and severe forms and gives an elaborate description of the diet to be ordered in each. Comment is also made on the various drugs which have been suggested, the administration of opium being especially commented on. Taking the book as a whole, we can cordially congratulate Dr. Williamson on the success of his labours, and our readers will find it a first-class book of reference.

The Wonderful Century; its Successes and its Failures. By ALFRED RUSSEL WALLACE. London: Swan Sonnenschein and Co., Limited. 1898. Price 7*s.* 6*d.*

A RECORD of the failures and successes of "The Wonderful Century" by a great thinker will command the perusal of all intelligent people. There are those who join issue with Alfred Russel Wallace on certain of his opinions—ourselves among the number—but few, we imagine, would find a place for polemics when considering the enormous advances made in this wonderful nineteenth century. Advances they assuredly are when we reflect upon the present state of the sciences—medicine, chemistry, physics, astronomy, geology, &c.—compared with the condition of our knowledge before Queen Victoria came to the throne. The successful study of these has placed the human race on a footing never reached before. Modern comforts are the fruit of it, accelerated modes of travelling, cheap as well as good food and clothing, rapid transference of thought and communication of ideas, and lightning communication of occurrences are all the outcome of man's curiosity and of this curiosity being followed up by successful discovery. In short, it is pre-eminently the age of discovery, and the progress of inventive genius is still maintained. Each discovery suggests fresh issues, fresh issues beget further discovery, and thus the giant strides in civilisation are made day by day. These are the "successes" which Mr. Wallace forcibly and delightfully recounts in 150 pages in Part I. of his book. But the "failures" occupy 230 pages in Part II. Judging therefore from the length of treatment of the two sides of the story the "failures" are in the majority and would thus belittle the title of the book. Over 100 pages—that is nearly a half of the whole section—are devoted to Vaccination a Delusion: its Penal Enforcement a Crime. Perhaps it occurred to the author that as he accounts vaccination as one of the most conspicuous failures of the age he could astutely find a place for it in the present volume to bring it into bold relief from his point of view with what he accepts as the "successes" of our time. Treated, however, at such a length it might have occupied a separate work. But without this section the "Wonderful Century" would have been a thin volume. Perhaps, after all, the title of the book is more attractive and agreeable to the average reader than vaccination. We have before expressed our admiration and respect for the great mental grasp of natural laws which, as everybody knows, Mr. Wallace possesses, but vaccination is a subject upon which he cannot claim to have any special knowledge, as he is neither a medical man nor a pathologist. Statistics, it has been said, may be made to prove anything. With Mr. Wallace vaccination "is no longer a question of opinion but of science, and I have (he concludes) the most complete confidence that the result I have arrived at is a statistical and therefore a mathematical certainty." He deals more broadly and liberally with

Digitized by Google

hypnotism and psychical research and "the neglect of phrenology," but again breaks out in Chapter xix., on Militarism, the Curse of Civilisation; in Chapter xx., on the Demon of Greed; and in Chapter xxi., on the Plunder of the Earth. Despite all this the work must be admitted to be a literary and scientific contribution of no mean order, as might be expected of an author who has written so abundantly, wisely, and fruitfully in the annals of one of the most important branches of science.

On Failure of Brain Power (Encephalasthenia), its Nature and Treatment. By JULIUS ALTHAUS, M.D., M.R.C.P. Lond., M.R.I. Fifth Edition, Enlarged and Revised. London: Longmans, Green, and Co. 1898. Pp. 270. Price 5*s*.

IN this work Dr. Althaus describes the condition commonly spoken of as neurasthenia but which he prefers to call encephalasthenia. It is an affection which notoriously involves much real suffering to patients and much inconvenience to their friends and often to their medical attendants. By some it is regarded as an exhibition of weakness merely requiring an effort of the will to "throw it off," by others as a "psychosis," a morbid mental condition, whilst by Dr. Althaus it is regarded as due to definite disease of certain special areas in the brain. After a historical sketch of the literature on loss of brain power Dr. Althaus gives a more or less popular account of the structure and functions of the brain. He describes with some fulness the "association centres" of Flechsig, which are shown in a diagram. These it will be remembered are districts in the brain which were shown by Flechsig to become myelinated much later after birth than the sensory centres, and he formulated the hypothesis that these were "association centres" connecting the various sensory spheres and specially subserving mental processes. The "posterior association centre" in the temporo-sphenoidal, parietal, and occipital regions is regarded as specially associated with high intellectual work, the "intermediate" as the association centre for language, and the "anterior centre" in the first and second frontal centre "contains the most essential elements of self-consciousness. It regulates our actions, enables us to judge our own performances, and tells us what to do and what to avoid. Disease of this centre changes the perception of the *ego* as an active being; it diminishes or destroys personal initiative, and prevents us from fixing our attention. Irritative disease of this centre causes either unmeasured self-conceit or self-depreciation, while decay of it leads to indifference, self-oblivion, and impaired judgment" (p. 65). All this may be interesting speculation, but it remains pure hypothesis now as much as when Flechsig first enunciated it. But Dr. Althaus speaks as if it were unquestioned, and when at the end he comes to treatment we find that he bases his treatment with great assurance on these hypotheses. "The principal remedy ..... is electricity." The constant current carefully graduated is to be employed and the electrodes are to be applied to these "association centres"—to the anterior centre "in cases where self-consciousness is exaggerated or perverted, self-control deficient or wanting, personal initiative and decision absent or diminished, and where it is difficult to fix the attention. ..... The posterior association centre has to be acted upon whenever the normal interpretation of external impressions is suffering and where the thinking power is more or less in abeyance, with absence or flight of ideas and foolish notions on persons and things" (pp. 262, 264). Dr. Althaus writes with much earnestness and appears to have convinced himself that the success which he claims to have had is due to restoration of these unproved and, we think, rather improbable functions enjoyed by definite areas of the brain. The book contains a great deal of information about the nervous conditions which are grouped under the term "encephalasthenia"; but the title of the book leads us to expect guidance on the nature and treatment of the disease, and on neither of these subjects do we think that Dr. Althaus's teaching is well founded.

A Text-book of the Practice of Medicine. By JAMES M. ANDERS, M.D., Ph.D., LL.D. London: The Rebman Publishing Company. 1898. Price 36*s*.

THERE seems to be no pause in the steady flow of new text-books of medicine and surgery, so that year by year the choice of the student becomes more embarrassing. He may well envy his forerunners of a past generation who were limited in their selection to two or three works of acknowledged merit which appeared in new editions with unceasing regularity. To-day, in addition to fresh editions of old favourites the student is confronted with entirely new books by teachers who must find it increasingly difficult to so compile their material as to justify the addition to the library of the medical school. No doubt, so rapid are the advances of knowledge, each successive text-book contains something which its predecessors lacked, just as the latest edition of such a work comes to bear very slight resemblance to the original from which it sprang. It is obviously impossible for any author of a text-book to impart much novelty into his work, other than the introduction of fresh facts furnished by the progress of science, but it is essential for the success of his teaching that it be well systematised, clear, and precise, with due regard to the relative importance of the facts with which it deals. The work before us seems to fulfil these conditions. It is free from redundancy, it is planned on an intelligible basis, and is obviously prepared by one who has had experience in teaching and knows the student's needs. The author is Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College, Philadelphia, and he writes with full appreciation of the bearings of modern science. We note, for example, the inclusion of lobar pneumonia amongst the infectious diseases, and the description of all forms of local tuberculosis, including pulmonary phthisis, under the general head of Tuberculosis. He gives clear directions of the bath treatment of typhoid fever, appraises the value of the antitoxin treatment of diphtheria, describes fully the hæmatozoal origin of malaria, the amœbic origin of dysentery, and so on. There is no need to discuss his chapters in detail, but we may call attention to the extensive introduction of tabular comparisons between allied diseases which summarise the leading points in their differentiation. We are not altogether convinced of the utility of such comparative lists, which are perhaps best left to the student himself to compile; but we must say that they are here judiciously drawn up and may prove of assistance to teachers if not to students. The book as a whole is very complete and it deserves a prominent place amongst medical text-books. It is, moreover, very well printed and illustrated and possesses a copious index.

BRITISH ASSOCIATION.—In connexion with the forthcoming visit to Bristol of the British Association for the Advancement of Science it is stated that the number of foreign guests promises to exceed all anticipations. In addition to the list of excursions already announced in THE LANCET additional ones have been arranged for Exeter, Plymouth, and Torquay. The visitors will begin to arrive in Bristol on Monday, Sept. 5th, and on the following day the Cabot Tower will be opened by the Marquis of Dufferin. The Presidential Address will be given on the evening of Wednesday, Sept. 7th, and the sectional meetings will commence the following morning.

THE LANCET.

LONDON: SATURDAY, AUGUST 6, 1898.

SIR T. GRAINGER STEWART, standing as successor to ALISON, CHRISTISON, STOKES, and ACLAND as President of the British Medical Association, may be excused for lauding his office and may be congratulated on his address. The address—a full abstract of which we were able to publish last week—was not in any sense a disclosure to the profession of new truths in pathology or therapeutics. It covered a large number of subjects affecting the relations and efficiency of the profession, any one of which might have occupied the whole of his time. But in his selection of topics and in the broad judgment which he passed on them it may safely be said that he expressed opinions which any of his illustrious predecessors would have approved. Some of our readers will not agree with him in his objections to a one-portal system. He recognises the demand for this system but thinks the legislature was well advised in retaining the many portals which exist. He considers that separately they are capable of being made to do good work; that while there should be a minimum standard it is well to have a variety of qualifications, some of a humbler sort and easily acquired, others of a higher order and more difficult to attain; and he thinks it would pass the wit of man to devise a method by which either for the whole kingdom or for each division of it one equitable and trustworthy entrance to the profession could be planned. These are very interesting but very debateable propositions. We are not prepared to say that they do not contain a good deal of truth which may be easily overlooked in a superficial discussion of the one-portal system, but it is certain that the many portals which now exist do not command respect either by the minimum which they enforce at the one end of the scale or by the higher standard which carries University honours and titles at the other. If the many-portal system is to be maintained two things are essential. The minimum standard must be more severely defined than at present and the General Medical Council must be entrusted with the function of determining whether the University examinations are what they pretend to be—that is, higher in standard than those which are supposed to represent a mere pass examination. One of the questions which every student of medical politics must feel to be pressing is whether any examination entitling him who passes it to a qualification to practise and to a place on the Medical Register should be of a really humble sort in the sense of being easy of acquirement. The humblest worker in the most squalid district has the same problems to encounter as the practitioner in the most fashionable district of London. Disaster and discredit will follow ignorance. We know the arguments for humble qualifications and we see how the druggist with no qualifications at all treats half the diseases of the public. But the remedy lies not in imperfect education and humble qualifications, but in that sound training which forms the true medical man and differentiates him from a mere dealer in drugs.

The part of Sir T. GRAINGER STEWART'S address which was most opportune and which commanded the widest attention was that in which he described the duty of the legislature in the prevention of disease. He pointed with just pride to the enormous progress which has been made in the reduction of the mortality from the principal groups of disease. The annual death-rate from disease in England and Scotland has fallen in less than fifty years by more than one-fifth. The proportion of deaths from zymotic diseases as compared with other causes has diminished by more than one-third. The treatment of disease of individual organs is much more successful than it was a few years past. Even the mortality of tuberculous diseases is less by one-third than it was in the sixties. We pointed out a few weeks ago that in Liverpool this was most unmistakably true. It seems more strikingly so in Glasgow, which once ran Liverpool hard in all which was unsavoury and unsanitary. Sir T. GRAINGER STEWART tells us that comparing the last seven years' mortality from tuberculous disease in Glasgow with that of the seven previous years the deaths from pulmonary tuberculosis are nearly one-fifth less and the life of those stricken is much longer. This fact alone justifies Sir T. GRAINGER STEWART'S statement that the country has awakened during the QUEEN'S reign to a sense of the benefits of sanitary legislation, without which such enormous saving of life could not have been effected. It need not be said that such legislation has been suggested by the medical profession and that the Acts which have been so instigated have been practically administered by the same profession. It might have been expected after an Education Act had been in operation for a quarter of a century, and such great results could be shown to have resulted from legislation inspired by medical science, that the public would have been eager to receive further teaching from the profession for the control of preventable disease. Here the President had to confess the limitation of popular intelligence and to point out, as he did most ably, the disastrous influence which is being exerted on the English public and the Parliamentary mind by a "comparatively small group of men" who have fastened on the subject of vaccination with a determination worthy of a better cause, have maligned the process, have belittled its advantages and have magnified and multiplied its slight risks. Sir T. GRAINGER STEWART is a generous and sanguine man and in spite of all which we have lately seen retains faith in the community coming to its senses and to a just appreciation of what it owes to the medical profession. We have not the same fears that he has expressed as to the inclusion of a conscience clause in the Vaccination Bill—our views are fully expressed in a leading article this week—but we fully endorse his claim that the medical profession has established its right to be heard with respect on all questions of public health, while the medical voice on the efficiency of vaccination is practically unanimous.

Digitized by Google

We must conclude, though we have not referred to all the subjects touched on by the President in his comprehensive address. He spoke in terms of praise of the work of the General Medical Council in raising the standard of preliminary examinations, in extending the period of medical studies, in its opposition to "covering" and other forms of unqualified practice, and argued for the extension of its powers. Not the least effective part of his address was that in which he discussed the medical organisations within the profession, and notably the British Medical Association, the objects of which are the promotion and advancement of medical and allied sciences and the maintenance of the honour and the interests of the medical profession. With the praise accorded to the Association and its work we concur. It is a great agency for good in the profession—too great a one to be made the tool of any small cliques or the subject of rash experiment. If it continues on its old lines with courage and discrimination it will deserve fifty years hence even more than it does now the praise accorded to it in Edinburgh by Sir T. GRAINGER STEWART.

THE Address in Psychological Medicine delivered by Sir JOHN BATTY TUKE at the concluding general meeting of the British Medical Association is in several ways very encouraging to neurologists. The speaker was certain of having a congenial and familiar theme whatever part of the wide field before him he might select for his subject on this occasion, and in discoursing on Modern Conceptions of the Etiology of the Insanities he was able to refer with justifiable satisfaction to the great progress which has been made in our knowledge of cerebral physiology and pathology. It is no new thing for the researches of the laboratory to bear fruit in the treatment of disease. The elucidation by Pasteur of the nature and effects of microscopic organisms paved the way for the practical work of Lord LISTER by which operative surgery has been revolutionised and the subsequent vast developments of micro-biology have profoundly modified our views with respect to the diagnosis and pathology of a most important class of diseases. In the case of diphtheria, for instance, laboratory methods of diagnosis not only tend to supplant clinical experience, but have introduced fresh complications into the problem by the discovery that the presence of pathogenic organisms is sometimes compatible with apparently perfect health. These are the triumphs of the microscopist and the experimental physiologist, but to those who have the responsibilities and anxieties of lunacy practice, whether as consultants whose advice is sought in doubtful cases of mental aberration or as superintendents of asylums for the certificated insane, it has long seemed as if the progress of scientific discovery did little or nothing to clear away the difficulties of their specialty. Even after the asylum treatment of insanity had been remodelled by the introduction of humane modern methods the heads of such establishments were, and still are, too often doomed to a system of indefinite expectancy in the matter of special treatment. The hardships of enforced detention may be alleviated by kind usage, frequent amusements, liberal and wholesome food, varied occupations, and hygienic surroundings, but it is undeniable that a considerable proportion of the inmates are incapable of improvement—a misfortune which is in some cases probably due to the fact that they have not come under medical observation until the malady was so far advanced that the signing of a certificate for their detention could no longer be delayed. Apart from epilepsy and congenital idiocy, the current classifications of insanity were purely psychological, until in course of time it came to be understood that a group of symptoms known as general paralysis—a condition which could often be recognised in a comparatively early stage—tended inevitably to progress by slow degrees to mental excitement, dementia, and death.

Since 1864, however, as Sir J. BATTY TUKE reminded his hearers, the combined labours of microscopists, physiologists, and pathologists have succeeded to some extent in lessening the influence of mere psychology on our conceptions of insanity and have partially replaced it by the surer basis of anatomy. For the names and merits of the foremost workers in this field we must refer our readers to the address itself, but there is no reason for disguising our satisfaction at the circumstance that the names of HUGHLINGS JACKSON and others of British nationality hold a good position in the honourable list. Let us turn now to the brief outline of their discoveries as given in Sir J. BATTY TUKE'S own words:—

"The observation round which all others centre is, to my mind, the demonstration of the mechanism by which impulses are carried from the periphery to the cortex and from the cortex to the periphery. We know that series of fibres exist which, starting from the entire surface of the body, from the muscles, and from the mucous membranes, are collected in the spinal cord and pass upwards to the optic thalami, whence—as demonstrated by FLECHSIG, whose observations have been confirmed experimentally by FERRIER and ALDREN TURNER—they are distributed in three systems to the cortex. ..... It is not necessary for our present purpose to consider where and how the transmutation of peripheral impulses takes place, but it is of importance to emphasise the statement that impulses are not generated in the cell body. As GOWERS says, the old battery idea must be thrown aside. ..... All impulses come from without, a fact which must have important bearings on the question of the adjustment of outer to inner relations. ..... Shortly after the methods of cutting and staining microscopic sections of nervous tissue were discovered the fact was elucidated that marked departures from health were to be found by microscopic examination of the brains of persons dying insane, and the results were embodied in the work of BEVAN LEWIS, in which not only were lesions described in the mass, but differentiation of special lesions in connexion with certain classes of insanity, were demonstrated. ..... In most of the recently-erected institutions for the insane at home and abroad we find separate hospitals provided for the treatment of acute cases. This surely marks the reduction of theory to practice. Instead of the subject of a recent attack of insanity being mixed up with the residuum of chronic cases he is placed in a separate institution, where he is submitted to systematic treatment on hospital principles."

So far Sir J. BATTY TUKE had been addressing himself mainly to specialists in lunacy work, but in concluding he foreshadowed a time when the importance of early treatment of mental disorder would be more generally recognised than at present. Timely treatment would of course have to be conducted largely by the family medical adviser, as

Digitized by Google

there is no prospect of the law permitting certification until the symptoms have become definite and well-established, but when the educated public come to know that mental disease is most amenable to treatment in its incipient stage, and that delay in obtaining medical advice is the worst possible policy, there is good reason to believe that certification may in some cases be dispensed with.

Now that the holiday season is once more upon us it may not be out of place to raise a protest against the tyranny of custom and conventionality. Holidays are not only pleasurable, but in many cases an absolute physical necessity. Still, this is no reason why we should allow ourselves to be tyrannised by the idea that we must take a holiday at a particular season and in a particular manner. Even though Society issues a ukase that everyone shall leave town before the end of August we are not absolutely obliged to obey this order. Instead of studying the edicts of fashion we should study the idiosyncrasies of the individual. Doubtless the country is very pleasant in the autumn, but town also is more agreeable during that season. Indeed, it occurs to us that for those who can afford to travel far enough midwinter may be the best time for a holiday. After all, is it not better, especially for those who have a tendency to diseases of the respiratory organs, to escape from the fogs and foul weather of winter than to leave town during the very best period of the year? In midwinter more sunshine and brighter sunshine can be enjoyed on the Riviera than is seen in England during the summer months. Those, therefore, who have reason to fear the English winter climate should postpone their holidays till November or January unless they are in the fortunate position of being able to take two holidays in the course of the year. It must be borne in mind that the custom of the summer holiday came into existence long before the invention of railways and steamships. In those days the difficulties of travelling on the Continent were very great. Only persons with large fortunes could hope to reach a semi-tropical climate during the winter and even then the fatigue of travelling for days, not to say weeks, in a diligence was so great that no delicate person could safely undertake such a journey. It was therefore quite natural that the best time of the year should be selected for the holiday season. Now, however, even families who possess but moderate means can enjoy two summers instead of one in the course of the year. The Riviera winter is brighter than the English summer. The journey South certainly costs more than the journey to any English, Scotch, or Irish resort, but life on the Mediterranean is cheaper—indeed, much cheaper. The very large and fashionable hotels are expensive, but there are many very good second-class hotels on the Riviera where complete board, including wine, can be obtained for 8*s*. a day. It is because these facilities for wintering in a warm, bright climate have only come into existence quite recently that summer still remains the holiday season. In time and for many people this custom might be altered and the holidays taken in midwinter so as to escape some of the worst features of the British climate.

Meanwhile, and for those who are about to leave home now, we would insist that a holiday should secure complete rest, and the best rest is a thorough change of scene and occupation. Above all, there must be no mental worry or over fatigue. Exercise is most beneficial, but the abuse of exercise is injurious. In this respect cyclists are particularly prone to overstrain themselves. In so far as cycles have induced persons, especially women, to take exercise when formerly they took little or no exercise they have undoubtedly contributed to improve the health of the population. On the other hand, many people have been injured by overstraining. In this respect there is a special danger in the organisation of holiday parties with cycles. If the persons composing the party were physically equal in strength and animated with the same spirit of moderation, such expeditions would be as beneficial as, doubtless, they are enjoyable. But this is rarely the case. Some are stronger than others; some find their pleasure in going far and quickly. The others, from a spirit of emulation or simply so as to be agreeable to their companions, also strive to go far and quickly. Consequently they overtax their powers and the holiday may do them more harm than good. The fable of the tortoise should be taken to heart. It is far better to lag behind to-day and live a long healthy life than to go "scorching" ahead at the risk of breaking down to-morrow. He laughs best who laughs last. There is more than one race to be run in life and he wins most who best husbands his strength.

These laws apply to the mind as well as to the body, though it does seem possible to work the mind much more than the body, as witness the ripe old age of great scholars, statesmen, lawyers, &c. But if such men as M. THIERS and Mr. GLADSTONE accomplished an immense amount of mental work they had also a wonderful faculty for rest. The secret of Mr. GLADSTONE'S long life was doubtless due to the fact that he was not only able to sleep easily, but that he was always ready to abandon even the most important, the most urgent task, and to lie down to sleep then and there, whenever he felt really fatigued. That is the true principle. No matter how disappointing or how humiliating to our pride we must stop, and stop at once, when we feel that we are doing too much. After all, a greater, a higher, a nobler strength is required to confess our weakness than to go struggling on. The youth who can calmly endure the jeers and taunts of his companions rather than attempt that for which he feels he is not physically or mentally fit will in the long run prove to be the better man. A holiday must be a holiday and a false pride must not be allowed to convert pleasurable, easy exercise into a painful strain, an injurious competitive struggle. Over-exertion has always been the accompanying danger and evil of all athletic games and sports, and this cause of injury is now more widespread because an enormous number of people who never indulged in athletics have become bicycle riders. It is, therefore, more than ever necessary to preach the doctrine of moderation. So, likewise, with regard to mental exertion. The man whose mind is overstrained by business responsibilities and worries must so plan out his holiday that it shall not occasion him any mental anxiety. In many instances it is the mind far more than the body which needs a holiday, and this fact should

Digitized by Google

be carefully considered. Consequently the holiday should be mapped out, not according to custom, fashion, or the example of friends and of society, but only according to the especial physical and mental requirements of the individual concerned.

THE Vaccination Bill was read a second time in the House of Lords on Tuesday last, and the committee stage was to be taken last night (Thursday). At the time of writing we are in ignorance of the fact whether it has or has not been allowed to pass the Upper House unaltered. There has been much frantic advice to the Peers to save the country by casting out the conscience clause which was inserted by the Government at the eleventh hour, but when we regard the majority by which the Bill passed its third reading in the Commons we do not see what ground there can be for such appeals. For it must be remembered that as it left the Commons the Bill was more in harmony with the recommendations of the Royal Commission than it was when first introduced, and be the motives for the change of front what they may it is equally certain that this change was advocated by the great majority of the speakers in the debate on the report stage of the Bill.

But some writers, and responsible ones, have not only appealed to the House of Lords to re-impose compulsion; they have called on the medical profession to speak "in no uncertain tones" in the same sense. We would venture to remind those who write so urgently that our profession has, with a unanimity rendered all the more striking by the fewness of those who hold a contrary opinion, never faltered in its conviction of the efficacy of vaccination. The pronouncement of the Royal College of Physicians of London that vaccination "*properly performed*" and "*duly repeated*" is the "only known preventive of small-pox" expresses these views. That is a proposition which no sophistry can dislodge, which is confirmed by the experiences of every epidemic and is endorsed by those whose office it is to combat such outbreaks by all the resources of science. The characters of small-pox—its high degree of contagiousness, the rapidity of its spread on congenial soil—defy the efforts to suppress it by isolation alone, or to arrest it in its earlier days of invasion; and if vaccination were not at hand to render its remarkable aid the disease would become as common and as widespread in this country as it was in times when sanitary science was unknown. Nor does the fact, dwelt on with so much unction by the anti-vaccinationists, that epidemics occur in so-called "well-vaccinated" communities, affect the truth of the proposition in the least. The medical profession are aware that vaccination does not afford life-long protection and it is because this Bill ignores the highly important factor of revaccination that it fails to secure our sympathy. To ensure a community having the full benefit of vaccination, then, the operation must be "properly" performed—that is, with every reasonable precaution and with thoroughness. The provisions in the Bill for the use of glycerinated calf-lymph and for domiciliary vaccination are intended to meet this condition. But vaccination must be also "duly repeated," and for this there is no provision in the Bill. And, further, the community cannot reap all its advantages, cannot feel secure in their immunity from small-pox, unless every single member has in compliance with these conditions been properly and repeatedly vaccinated. How is this general vaccination and revaccination to be secured? This is a question for the State, not for the medical man, and when politicians call on us to show them the way they are inciting us to step outside our legitimate province.

The whole question may be summed up in a few words. The object aimed at by the State in legislating on vaccination should be to secure the benefits of this safeguard to the greatest possible number of persons. This can be done with varying degrees of success by one of three courses: (1) universal compulsion under penalties; (2) compulsion limited in extent by mitigation and restriction in the number of penalties; or (3) optional vaccination. The first plan, still effectively carried out in Germany with the best results, has been tried for many years in this country with a gradually increasing want of success. The strong opinion expressed by the Council of the Royal College of Surgeons of England in 1893 and reaffirmed the other day in favour of the continuance of such legislation may be a counsel of perfection, but can be nothing more. *Nulla vestigia retrorsum*, and the practical man, especially if he has perused the evidence given before the Royal Commission on Vaccination, must be convinced that in regard to vaccination the policy of "thorough" compulsion is no longer possible in this country. We may deeply regret the fact and may seek to explain it away as the work of misguided fanatics, but it is none the less real and the continuance of the old plan only tends to bring the law into contempt. None of us are blameless in this matter. We have condoned laxity in the performance of vaccination. We have not striven to set forth its great advantages or to diminish its attendant risks. These have been unscrupulously magnified until parents with no fear of small-pox before their eyes have preferred to resist the law rather than subject their children to the supposed dangers of vaccination. The second alternative, modified compulsion with restricted and mitigated penalties, is what the Government Bill intended, coupled with provision for increasing facilities for and diminishing the risks of vaccination. It was hoped that many objections would be removed by these concessions, but the opinions expressed in the House of Commons led the Government to change their plans and to adopt the third alternative and by the introduction of a conscience clause to practically make vaccination optional and not compulsory. This, which has been variously characterised as a piece of political expediency or as yielding to the clamour of a clique, may nevertheless prove to be the most statesmanlike course, though no medical man can view with equanimity the possibility of an outbreak consequent upon a liberal use by the public of the right to conscientious objection. However, if the plan were to reduce the number of recalcitrants it would not attain the objects aimed at unless it were accompanied by provisions for a similar enforcement of revaccination of adolescents. Therefore, we shall not regret the withdrawal of this Bill.

Annotations.

"Ne quid nimis."

THE FRENCH GOVERNMENT MATCH FACTORIES.

THE Home Office has just issued a short report prepared by Dr. Thomas Oliver on the French match works at Aubervilliers, Pantin, and Marseilles, which he visited during the course of the month of June. From this interesting document we gather that the prevalence of phosphorus poisoning has been very materially reduced since these factories were taken over by the French Government and the trade in matches was converted into a State monopoly. But this improvement was not brought about at once; it was not till 1896 that the French Government appointed a Commission to investigate the matter. The question with which Dr. Oliver does not deal, but which is nevertheless of some practical interest, is whether the action taken by the French Government was more prompt and more effective than was our action in England. Nevertheless from the facts stated in the report it would appear that such is the case. For instance, at the coroner's inquest concerning the death from lead-poisoning of a "dipper" named Henry Wagstaffe, a witness having admitted that he did not read the warnings posted in accordance with the Factory Act, the coroner, Mr. Wynne E. Baxter, exclaimed: "It is a great pity when the Government try to protect you people you won't take the trouble even to read the rules." Dr. Oliver, in his report on the French State factories, when alluding to similar rules for the protection of the health of the workpeople, says that they have "to be read out aloud on the first Saturday of every month, those in charge inscribing in a memorandum-book the date upon which this monthly reading took place." These rules for the French match factories enjoin that no food or drink be allowed in the workshop, but must be left in the dining-room; that before meals the working clothes must be left in the cloak-room and the workpeople must wash their hands with soft soap and water and must gargle their mouths with a gargle specially provided for that purpose. Then only are they allowed to eat. The same precautions are taken on their leaving the works. Further, it is enacted that no one shall be employed under sixteen years of age and that they must first be examined by the medical man, who must certify that they are free from bodily infirmity and contagious disease, that they have been vaccinated or have had small-pox, and that the state of the teeth is good. As a result of these precautions among the 575 men and women employed at the Pantin and Aubervilliers works there has not been a single case of phosphorus poisoning during the period Dec. 1st, 1896, to Dec. 1st, 1897. Yet during that time the methods of manufacture have not been altered, and the ventilation, though effective in the "dipping," was not effective in the "boxing" department. Dr. Oliver concludes that though formerly there were many cases of poisoning there is now apparently a reduction, at least in the severer cases. This is due to raising the age of admission, to medical examination, subsequent close supervision, repeated dental examination, the personal cleanliness of the workers, and immediate suspension on first symptoms of illness, with allowance of two-thirds of the salary while the employé is away from the works. Dr. Oliver further credits the French Government with doing all in its power to discover better methods of manufacture. Chemists and inventors are paid out of the public purse to study the matter, and the result is that a match which will strike anywhere and yet which is free from phosphorus has been invented, though it has not yet become a commercial article.

QUESTIONS OF MEDICAL SECRECY.

TWO questions relating to the observance of professional secrecy have lately been discussed in France. The first was as follows:—Should a medical man reveal to a mother the fact that her daughter is syphilitic? On the one hand it was maintained that if the girl consults the practitioner on her own account he is absolutely bound to secrecy. On the other hand it was held that if the mother brings the girl—who is very probably a mere child—to the practitioner, he has to consider that she is not likely to appreciate the gravity of the disease or the risks of contaminating other members of the family as well as her mother can, and his own common sense must guide him under the circumstances of the particular case as to whether it may not be for the patient's own advantage as well as for that of the family to explain matters to the mother. The other question relates to a case which has recently occurred. A practitioner having been sent for to a family whose regular attendant he was became a witness of a violent scene between husband and wife terminating in acts of cruelty. He withdrew without giving any professional advice or any prescription. Subsequently he was summoned to give evidence in a court of law in connexion with a demand for legal separation of the husband and wife, but refused, claiming that he was bound to professional secrecy, which, it must be remembered, is more obligatory, from a legal point of a view, in France than in this country. The court, however, did not admit the plea and fined him 10 francs. In view of an appeal against this he asked for the opinion of his professional brethren as to his action. Different views were expressed, some holding that what he saw was not a secret confided to him as a medical adviser, for in fact he was not acting in a professional capacity at all and therefore could only have been an ordinary witness, while others thought that having been for a long time the family professional confidant and having been sent for as a medical man he was bound not to divulge what he knew, especially as he might have been pressed in the witness-box to mention circumstances which had come under his notice in previous visits which had been strictly professional. Doubtless, too, it was urged it would create a bad precedent if it were established that one of two disputants might send for a medical man simply for the purpose of ensuring the presence of a witness to some *fracas*, for this would be a degrading position for a medical man, whose work is certainly not that of a professional witness. The case, as a matter of fact, came to no definite conclusion, being withdrawn by the parties themselves.

THE EFFECT OF TELEGRAPH WORK ON THE HEALTH.

IN a paper read before a meeting of railway telegraph clerks in Manchester on March 26th Mr. J. T. Hull, president of the Railway Telegraph Clerks' Association, gave so unfavourable an account of telegraph work in relation to the health of the operators that he not only described it as being responsible for many bodily ailments, but said that there was an extreme probability of its "being the most deleterious in its effects upon the operator of any trade or profession hitherto regarded as dangerous.' Telegraphy, he said, is essentially a mental action, involving principally the auditory nerves. The development of this faculty in a proficient telegraphist may be approximately ascertained by a simple calculation. In ordinary working—that is, reading twenty words per minute, the operator distinguishes about 150 alternations of pitch (on the needle) or duration of beats (on the sounder) and under pressure it is said that as many as 450 may be accomplished. In telegraphy there is also the translation of

Digitized by Google

the auditory symbols into visual symbols—i.e., the writing, which implies mental exertion. While normally 120 discriminations per minute may be made of varying sensations the telegraphist never does less than 150 and may do 450 per minute. Without taking the extreme case it may, therefore, be safely asserted that the auditory faculties of telegraphists are about 2½ times as sensitive as those of ordinary persons. In telegraphy it is the uninterrupted continuance of nerve stimulation, the monotony of sound, and the fixity of attention which are injurious, the work being pre-eminently the reception and mental arrangement of monotonous sounds and demanding close and arduous attention. That this condition of concentrated attention is most acutely enervating is the unanimous testimony of all physiologists. During a pressure of work the interference with normal respiration, the increased action of the heart, and the rush of blood to the head may be readily observed. These effects are most noticeable during a spell of rapid sending and are probably due to the physical movements making the attentive effort more onerous. The prevalence of phthisis among telegraphists is clearly shown in the following tables taken from the evidence given by Mr. Garland before the Royal Commission appointed to inquire into the grievances of the Post Office employés:—

TABLE A.—*Showing Comparative Percentage of Mortality from Respiratory Diseases, with Deaths after Fifty-five Years of Age Excluded.*

—	Phthisis.	Other respiratory diseases.	All respiratory diseases.
All adult males	13·8	10·6	24·4
Telegraphists	46·6	12·9	59·5
Grinders (cutlery)	33·1	24·2	57·3

TABLE B.—*Showing Comparative Percentage of Mortality from Respiratory Diseases, all Ages from 15 up to 65.*

Ages.	All males.	Telegraphists.	Grinders.
15 to 25	3·5	18·4	4·3
25 to 35	4·9	23·1	8·3
35 to 45	5·3	12·0	13·6
45 to 55	5·3	4·3	17·7
55 to 65	5·4	0·5	13·4
Over 65	8·2	0·5	6·7
All ages	32·6	58·8	64·0

Mr. Hull further said that he suspected that many telegraphists suffered from a modified form of chorea consisting of a twitching of the fingers in accordance with the telegraphic symbols of the alphabet.

GOFF *v.* GOFF AND GORDON.

WE do not comment upon this case because Dr. Bruce Goff, who has recently obtained a divorce from his wife under circumstances which have been fully detailed in the lay press, happens to be a medical man, but because an accusation was brought against him by his erring wife, one which, had it received the credence of the jury, would have properly ruined his professional career. Mrs. Goff's counsel admitted the indiscretion of his client's conduct and the mendacity of her letters, while all the evidence showed that excellent opportunities were given to the co-respondent, a man with a significant past, to go all lengths with her; but counsel was instructed to deny the commission of adultery and to accuse Dr. Goff of performing illegal operations upon the respondent for the prevention of pregnancy. Such a deed, though it would not have been an excuse for adultery, would have most certainly palliated in an outraged wife some actions of resentment or reprisal and would, therefore, if proven, have much embarrassed Dr. Goff in his attempts to obtain legal relief. The jury with no hesitation whatever, while finding the respondent and co-respondent guilty of adultery, acquitted the petitioner of the odious act of cruelty to which his wife stated that she had been compelled to submit. We sympathise with Dr. Goff in the painful publicity to which his domestic life has been exposed and in the severe interpretation which was put by the learned judge upon his unwillingness to believe the woman he had married to be utterly unworthy and vicious; but we congratulate him heartily upon the verdict that exonerates him from the disgusting charge of procuring criminal abortion upon his own wife.

ANÆSTHETICS AND UNREGISTERED DENTISTS.

DR. R. C. BUIST of Dundee recently wrote a letter to the General Medical Council with reference to the practice of registered medical practitioners administering anæsthetics for dental practitioners not on the Dentists Register, and received the following reply from the Registrar of the General Medical Council:—

"That the members of the Dental Committee agree with the opinion expressed by the Executive Committee that the practice referred to in Dr. Buist's letter is most reprehensible, and recommend that if a charge of 'covering' in connexion with such administration of anæsthetics were brought before the General Council it should be entertained and investigated."

We take it that this recommendation really amounts to a guarantee that such a charge, if brought, would be investigated. It may be said that if registered medical practitioners are prohibited from administering anæsthetics this function will be performed by unregistered practitioners and the risk to the patient, never a negligible quantity, will be proportionately increased. We do not, however, think that this is a danger of which it is necessary to take serious account. Administration of an anæsthetic by an unqualified person is too risky an operation for either the dentist or his assistant to undertake and the probabilities are that he will either operate without an anæsthetic, which will not tend to increase his practice, or will send his patient away to some other practitioner.

HÆMOPHILIA.

IN the July number of the *Birmingham Medical Review* Dr. E. A. Sadler gives an interesting account of a family two generations of which suffer from hæmophilia, the preceding generation having apparently been exempt. The present head of the family is a widow, sixty years of age, living in Ashbourne, Derbyshire. Her husband died about three years ago from senile decay. They were, as far as they knew, quite unrelated before their marriage, thirty-seven years ago, before which time the woman (who, like her husband, comes of a family long established in the district) worked hard in farm service. She has had 16 children, 3 of whom died from infantile complaints in the first few days of life. The remaining 13 comprise 8 boys and 5 girls, the eldest of whom (a boy) at the age of three years, when apparently in perfect health, fell and bit off the tip of his tongue; the bleeding could not be stopped and death occurred on the fourth day. The next two sons and their children have not shown any tendency to the diathesis, nor has the fourth son. The fifth son died at the age of three months from "sunstroke." The sixth son was noticed to become bruised very easily at the time of his first attempts to walk. When he was nearly seven years of age the cutting of a tooth led to hæmorrhage which proved fatal

Digitized by Google

after a week's duration. The seventh son, now aged twelve years, has never bled or bruised. The eighth boy early developed the tendency to bruise, but it is diminishing year by year. He has had several troublesome attacks of epistaxis. The joint affection of hæmophilia first showed itself in him at the age of three years. He has had repeated attacks since and they always begin suddenly in the night. The well-known fact that the girls of a family do not themselves exhibit the hæmorrhagic tendency, but that they transmit it to their male children, appears in the present instance. Both the first and second daughters have always been perfectly healthy; they are married and have had each two boys; three of these children are alive and present marked hæmorrhagic symptoms, the remaining one died at the age of three years from a combination of epistaxis with bleeding from the ears and mouth.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

WE report elsewhere the proceedings of the meeting of the council of the above fund which was held on Wednesday and which was presided over by Sir Sydney Waterlow, Bart., in the unavoidable absence of the Lord Mayor. The meeting was well attended and the council refused to be much discouraged by the fact that they have £5000 less to distribute than in the previous year. Sir Sydney Waterlow is doubtless right in regarding the smaller collection, and that also of last year, as due directly to the temporarily distracting influence of the Prince of Wales's Fund, It will be noted that Sir Henry Burdett does not accept Sir Sydney Waterlow's theory of the deficit. When such doctors differ it is a pity that the council did not accept Dr. Glover's suggestion, and ask its Distribution Committee to investigate and report on the causes of the diminished collection. It is certain that His Royal Highness the Prince of Wales would be the first man to regret that his fund should in any way interfere with the success of that Hospital Sunday Fund of which he is himself vice-patron.

PUBLIC LAVATORY ACCOMMODATION FOR WOMEN AND CHILDREN.

A CORRESPONDENT recently wrote to the London County Council pointing out the imperative need which exists in many parts of the metropolis for further free lavatory accommodation for women and children and suggesting that buildings of this description were urgently needed at among other districts the Elephant and Castle. A copy of this letter was forwarded to Dr. Waldo, the medical officer of health of St. George's, Southwark, who made a special report to his vestry on the subject, in which he drew the attention of the vestry to the fact that he had urged the construction of new public lavatories in his reports for 1895, 1896, and 1897. At the present moment there is only one public lavatory for women—namely, that situated in New-alley near the parish church. Plans have been passed by the vestry for the erection of one additional lavatory for men only at the Obelisk and lavatories for both sexes at the junction of the Old and New Kent-roads. As regards accommodation for women alone tenders have been received for the construction of two—at the junction of the two Kent-roads and near the new public library respectively. Dr. Waldo, however, considers that even when these three have been built there will still be need for more owing to the density of the population. There can be no doubt as to the paramount necessity for conveniences of this kind. The want of them—and undoubtedly there is a great want in our overgrown city—is a fruitful cause not only of danger to health but of offences against decency. But we are not so sure that they should be provided by local efforts. Surely their cost should be a charge upon the whole of London, even as the buildings are used by the population of the whole of that city.

THE REPORT OF THE SELECT COMMITTEE ON PETROLEUM.

WE have received the report of the Select Committee on Petroleum, and propose to give the subject the full attention which it deserves at a later date. Meanwhile we may say that the Committee held 53 sittings and examined 85 witnesses, the latter including scientific experts, traders in and manufacturers of both oil and lamps, and public officials. The final recommendations of the Committee included the following points. That the flash point should be raised to 100° F.; that there should be statutory powers to enable the Secretary of State to issue orders affecting the manufacture and sale of lamps; and that information should be spread among the public as to the nature of petroleum and the management of petroleum lamps.

HAMPSTEAD HEATH EXTENSION.

ABOUT £4000 is still required for the completion of the purchase of the Golder's Hill Estate, adjoining Hampstead Heath, and seeing the great boon which the acquisition of this site would confer upon the metropolis we trust that the money will soon be forthcoming. It is confidently hoped by the committee in charge of the fund that they will be able to hand the control of the estate over to the London County Council within the next four weeks and the Council will then decide whether the house and gardens shall be retained as part of the park and dedicated to the use of the public. A scheme, which certainly merits careful consideration, is on foot to turn the house into a natural history and botanical museum in connexion with the Council's technical education work, and the conversion of the gardens and rosery into a botanical garden for students and the public.

THE DEATH OF PRINCE BISMARCK.

THE death of the real founder of the modern German Empire removes from the purview of this world the most prominent figure of the latter half of the present century. With general politics we are not concerned, and it is a happy coincidence that at the time of the death of him who wrought so sore a blow to France a congress should be sitting in Paris discussing the internationally important question of tuberculosis, a disease the real nature of which was first made clear by the researches of a German. Bismarck died in his eighty-fourth year after a life of the most unremitting toil in both mental and physical fields, but his enormous store of vitality enabled him to undergo and recover from fatigue which would have broken down an ordinary man. He could always eat, drink and sleep and so was enabled to recuperate very quickly, a faculty he showed with that other great leader of men, Gladstone. Like so many great men, Bismarck lived too long for his own happiness and glory. He found Germany a collection of petty principalities and powers; he made it a mighty empire, with its foundations, according to the old mediæval rule, consolidated and laid in blood; but inasmuch as the building was greater than a mere bridge or dwelling-house, so was the sacrifice not merely that of a dog or even a human being but of thousands of men, millions of money and the tears of two nations. Of his methods we need say nothing here; suffice it to say they were successful. But as is inevitable when two strong wills clash and the one is the ruler and the other the subject, it is the subject who has to yield. Bismarck brought the German Emperor into being, and, like Frankenstein, his creation overcame him. There is no need to dwell upon this: let us only remember him as a master statesman,

Digitized by Google

a man of unswerving will, a faithful and devoted servant to his country, who gave his whole life to forwarding her interests.

THE EDINBURGH UNIVERSITY CLUB.

THIS club held its August dinner at the Café Royal under the presidency of Dr. Aldren Turner, who, in proposing the toast of the evening, "Prosperity to the Club and our Alma Mater," spoke very clearly of the continued prosperity of the University in spite of the growing competition of other schools and the increased stringency of the preliminary examinations in the Scottish universities. Professor Chiene was present, to the obvious delight of the members, and enlivened the proceedings by several anecdotes and by his speech in proposing the health of the chairman. The guests included Mr. Bland Sutton who replied to the toast of their health, proposed by Dr. Glover.

FOREIGN DEGREES.

MR. J. W. SIDEBOTHAM, M.P. for the Hyde division of Cheshire, has introduced a Bill into the House of Commons which was read a first time the other day. The Bill, which is a short one of five clauses, makes it compulsory for every person who attaches to his name the degree of Bachelor, Master or Doctor in any faculty in which degrees are granted —unless such degree has been received from a British university or from any authority in the United Kingdom which confers degrees by virtue of a Royal charter or by the sanction of the Crown or of Parliament—to clearly indicate the source from which such degree has been received under a penalty of forty shillings and costs. The term "degree" shall mean and include any letters or abbreviations which are commonly used to signify the degree of Bachelor, Master or Doctor of any faculty in which degrees are granted. This Bill is evidently drawn on the same lines as the Medical Act—i.e., to enable persons to distinguish between true and false degrees. It is good as far as it goes, but it does not go far enough. The gentleman who calls himself M.D., U.S.A., or D.D. of the National University of Chicago, will still continue to deceive the ignorant and foolish, neither, so far as we can see, will it affect the ingenious persons who put M.B. after their names and when challenged say they do not mean that they are Bachelors of Medicine but only Medical Botanists. If a "degree" is received from no source at all it is impossible to indicate a source. However, the Bill is a step in the right direction.

THE NATURAL HISTORY MUSEUM.

IT is announced that the trustees of the British Museum have appointed Professor E. Ray Lankester to be director of the Natural History Department in the room of Sir William Flower, who retires at the end of September. We sincerely congratulate Professor Lankester upon this newly-conferred honour, all the more because, though not a medical man himself, he is the son of one and the brother of others and because his scientific pursuits have been so directly ancillary to medicine. He has been a Radcliffe Travelling Fellow of the University of Oxford and is well known as the writer of various works upon zoological and biological science. More and more as knowledge increases do we find light thrown upon pathological processes, solutions—or, at any rate, a clue to them—of various medical problems, and explanations of puzzling questions by a reference to biology. The birth, the progress, the degeneration, and the death of the organism, from the highest to the lowest, is in miniature the replica of the life-history of the race; the phylogeny is set forth in the ontogeny. So we physicians and surgeons—for whom with all our knowledge so much still exists which is dark—owe a debt of gratitude to those who have devoted their lives to the study of biology, and such a one is Professor Edwin Ray Lankester. His appointment is a guarantee that the reforms set on foot by Sir William Flower will in no way deteriorate in the hands of his successor and that the magnificent collection housed in South Kensington will be kept up to, if not exceed, its present pitch of excellence.

INCISION AND DRAINAGE OF PULMONARY CAVITIES.

AT a meeting of the Royal Academy of Medicine of Turin, reported in the *Gazzetta degli Ospedali* of July 17th, Dr. Bozzolo described two cases of successful surgical treatment of tuberculous cavities of the lung. One of the patients was a boy, eleven years of age, who in August, 1897, was found to be suffering from a cavity in the lower part of the right lung, and on whom an operation was performed by Professor Carle in the following December on account of threatening pulmonary gangrene. The Roentgen rays showed that the heart was displaced to the left and that the base of the thorax was dark, as if from localised empyema, but exploratory punctures gave no result. At the operation pleural adhesions were found, the lung was dense, and the cavity was deep and was situated higher than percussion seemed to indicate. The cavity was drained; the patient recovered rapidly and is now quite well. The second case was that of a man, thirty-six years of age, a brother of whom had died from tuberculosis. In March, 1897, he suffered from cough, fever, bronchial catarrh, weakness and emaciation, and could lie only on his left side or on his back. There was a cavity in his right lung and his expectoration was purulent, but Koch's bacilli were not found. The lung was incised but no adhesions were met with, and the man nearly died from pneumothorax succeeding the operation. Two months afterwards a larger and higher incision was made, firm adhesions being encountered. Exploratory punctures after many attempts resulted in the discovery of a small cavity containing pus, situated at some depth and communicating with another larger one. Drainage was followed by complete recovery. Both of these patients were present at the meeting.

SMALL-POX AND VACCINATION IN THE ESTON URBAN DISTRICT.

ESTON is an urban sanitary district on the south of the Tees and a little eastward of Middlesbrough, and it apparently derived its small-pox infection from the same menagerie from which, it is largely believed, the Middlesbrough outbreak started. There have been up to the date of the report which Dr. G. C. H. Fulton, the medical officer of health of Eston, has just presented to his sanitary authority 23 cases, and of this number of patients 20 were vaccinated and 3 unvaccinated. The fatality-rate amongst the vaccinated was 15 per cent. and amongst the unvaccinated (3 cases only) 100 per cent. Eston is stated to be a well primarily-vaccinated community, and this statement, though the total number of cases is small, is borne out by the fact that amongst those attacked there were but 2 under the age of ten years. No person who had been re-vaccinated contracted the disease nor did anyone who was brought in contact with the patients at the hospital. In contrast with this immunity Dr. Fulton mentions that at a neighbouring hospital under his care the only persons brought in contact with the patients who contracted small-pox were three who had not been revaccinated. Fortunately at the beginning of the outbreak isolation accommodation was in readiness, and vaccination and revaccination of the whole district were quickly arranged for. The inmates

Digitized by Google

of infected houses were quarantined for a fortnight and all those who had been exposed to the disease were at once vaccinated. Dr. Fulton reports that the modifying influence of vaccination on those attacked was very obvious, the eruption abating early and there being an almost total absence of secondary fever.

OVERCROWDING IN RAILWAY CARRIAGES.

THE question recently asked in Parliament by the Member for East Northampton on the overcrowding of railway carriages which prevails at certain hours of the day on London and suburban railways calls attention to an evil which has long been crying for remedy. Those whose lives are passed in the country or in the smaller provincial towns of England can have no conception of the condition of the suburban railways of London between 5 and 7 o'clock in the afternoon from Monday to Friday, for no other town in England relies so much on railways for intercommunication between its various districts. In no other town are the distances to be traversed so great, and in no other town is the travelling public so enormous. How is that public to be carried? That is the problem which the companies have to solve and it is not too much to say that hitherto they have for the most part entirely failed to solve it. During the busy hours of the day on the District, the Metropolitan, and the North London Railways, to name only a few examples, the passengers in third-class carriages are packed in their compartments in a manner in which it would be illegal to pack cattle. Let anyone stand on the platform at Charing-cross or Victoria on the "Underground" Railway and examine the trains going westward as they enter and leave the station at about 6 o'clock and he will see compartment after compartment crowded in a manner which is fatal to comfort and most inimical to health. The air space of a third-class compartment on the "Underground" Railway is by no means excessive for the ten passengers whom it is "constructed to seat." If to these be added the five passengers standing up and absorbed in the desperate effort to maintain their equilibrium as the train sways to and fro, a state of things is disclosed which calls for the interference of some humane or philanthropic society if not of Parliament itself. We admit the difficulty of the task which the railway companies have to perform. There must be great pressure of traffic at certain hours of the day when all the world is hurrying either to or from its business. It is easy to reply offhand that the companies must run more trains or longer trains, but—at least, as far as the District Railway is concerned—there are very serious practical and financial difficulties in the way of any change in either of these directions. On the busiest section of this line no more trains could be run with safety. They already follow one another as closely as the conditions of working will permit and the interval of time allowed between each train could hardly be further reduced without risk of disaster. The running of longer trains, on the other hand, would require longer platforms and the cost of that improvement is considered by the company to be prohibitive. Railway companies, after all, must consider their dividends. Here, then, we have an *impasse* and the only way out of it seems to be to build more railways. This is now being done as rapidly as may be. The Waterloo and City line which has just been opened will do something, though not much, to relieve the congestion of traffic on the District Railway between Charing-cross and the Mansion House, while the Central London Electric Railway, when it is opened, will do the same for a considerable section of the Metropolitan. But experience has shown that the opening of new suburban railways in London, far from relieving the traffic at the centre, rather tends to increase it. The greater the facilities for travelling from the suburbs to the City the more people flock to the suburbs and by consequence the greater the pressure of traffic upon the railways during the hours when men are going to and from their business. It is a question, therefore, whether even legislation itself can find a way out of the difficulty in which these railways are placed during these hours. In one thing, however, these railway companies seem to us to have failed in their duty to the public in this question of overcrowding. They do not appear to have reckoned with the enormous growth of Sunday travelling in London in recent years. At certain hours of the day on Sundays on many of our local lines there is a pressure of traffic which the companies not only do not attempt to meet but seem determined to ignore. For this there can be no possible excuse. It is absurd that railway companies should run fewer trains on Sunday than on week-days unless they are sure of carrying fewer passengers, and it is the business of the officials to see that the trains on that day are not so far reduced that they cannot comfortably accommodate the traffic which every Sunday brings them. This is not a case of accidental overcrowding on one or two days in the year due to exceptional circumstances, but of a constant and apparently deliberate refusal on the part of the companies to provide proper accommodation for the regular needs of the day. It is unnecessary for us to point out here how entirely contrary to the first principles of hygiene such overcrowding is and how essential it is that it should be avoided as far as possible. The growth of Sunday travelling in London may or may not be a good thing, but that is a question with which the railway companies have nothing to do. Their duty is to provide reasonable accommodation for those who wish to travel. A railway company cannot be permitted, either from indolence or a desire for larger dividends, to ignore this duty wherever it is possible to perform it.

THE FOOL ON A CYCLE.

IN spite of the object lessons which inquests on cyclists give and in spite of police prosecutions the number of cycling accidents increases, while it is evident that the majority of the casualties follow upon reckless riding. The commonest cause of disaster is, of course, want of caution in descending hills. The effort of the National Cyclists' Union to prevent accidents by placing notice-boards at the top of all dangerous hills is treated with contempt by many cyclists, who regard such boards as a playful invitation to put up their feet and "coast" to the bottom. In a recent inquest held at Hull the coroner, Mr. Luke White of Driffield, is reported to have said that if cyclists persisted in disregarding notices which were exhibited for their personal safety it might be necessary for the protection of the public to require all cyclists to dismount on going down hills which were marked "dangerous" and to inflict a heavy fine in every case where the notice was disregarded. We quite agree with Mr. White. "Put a fool on a cycle and he will ride to destruction," makes a very good reading of an old saw and describes a situation which we can regard with equanimity. But when the fool on his way to his proper destination thinks well to smash into other people it is time to put a limit to his folly.

IN the presence of a great sorrow sympathy, however well intentioned, is all too inadequate and yet it is the only thing which can be offered. The profession is well acquainted by this time with the sudden and heartrending calamity which has overtaken Mr. Henry Power and his family in the death of his daughter and granddaughter by drowning. They were swept off the east pier at Whitby by a wave of unusual size and height and owing to the state of the sea all efforts to save them proved useless. Mr. Power himself made an heroic effort, but all unavailingly. His

Digitized by Google

daughter, Miss Lucy Power, will be known, by name at any rate, to most of the profession owing to the portrait painted by her of her father which was exhibited in the Academy of 1897. We are certain that these few words in which we express our heartfelt sympathy with the relatives of the deceased will be only giving expression to the general feeling of the medical profession of which Henry Power has for so many years been a prominent member. Specially does this apply to members of St. Bartholomew's Hospital, where he is, though no longer an active member of the staff, lovingly remembered in the wards and the lecture theatre.

DR. J. P. STEELE, for many years a contributor to THE LANCET, mainly in the field of Italian medicine past and present, has had since May last to suspend his contributions owing to a severe accident to his left eye. No effort was wanting, first on the part of Dr. Pereyra of Florence and then of Professor Haab of the Zürich School of Medicine, to save the injured organ, but after some weeks of skilful and steady treatment it was found that the lesion, mainly in the ciliary region, could not be repaired and that sympathetic inflammation was threatening the sound eye. Enucleation was therefore resorted to and successfully performed by Professor Haab in his private clinique at Zurich on July 6th, since which date Dr. Steele has made complete recovery, the right eye being now out of danger, affording every probability of his early resumption of work.

AT Leeds Assizes on July 29th Henry Yeo, editor of a local paper called *Spy*, published in Manchester, was sentenced to twelve months' imprisonment with such hard labour as his health would allow for publishing libels concerning Mr. W. Bevan Lewis, medical superintendent of the Wakefield Asylum. The prisoner's wife, who was indicted for circulating the libel, was bound over.

THE treasurer of Guy's Hospital has received an anonymous donation of £6000 from one who listened to Mr. Balfour's speech on the occasion of the distribution of prizes in the Medical School, with a request that the governors would use the sum for the purpose of the endowment of medical research.

DR. J. C. THRESH, Medical Officer of Health to the Essex County Council, has been appointed Lecturer on Public Health at the London Hospital Medical College. The new laboratories and public health museum now being provided at this college will be ready by the commencement of the winter session.

AT Netley Hospital on July 29th a beautiful tablet erected to the memory of Sir William Mackinnon, late Director-General, by the medical officers of the British Army, was unveiled without ceremony.

KING'S LYNN.—On the reappointment of Dr. C. B. Plowright as medical officer of health the Freebridge Lynn Rural District Council raised his salary from £82 10*s.* to £100 per annum. The District Council also resolved that steps should be taken to add, if possible, phthisis to the list of notifiable infectious diseases.

SANITARY INSPECTORS' ASSOCIATION.—The annual meeting of the Western Branch of the Sanitary Inspectors' Association was held at Exeter on July 16th. A public meeting took place after the annual meeting at the Guildhall, at which the Deputy Mayor presided, supported by Dr. Woodman, Dr. Kempe, and Dr. Pickard. Mr. Cameron contributed an interesting paper on the Treatment of Sewage by the Septic Tank System. A public luncheon followed, which was numerously attended.

THE BRITISH PHARMACOPŒIA.

VIII.[1]

CONCLUSION.

IN our second article we referred to some of the more important changes in strength and dosage. A change has been made in the most active and important group of Galenical preparations with which the practitioner should be familiar. The following liquors are now made with the intention of being 1 per cent. solutions—viz., Arsenicalis, Arsenici Hydrochlor., Atropinæ Sulphatis, Morphinæ Acetatis, Morphinæ Hydrochlor., Morphinæ Tartratis, Potassii Permanganatis, Strychninæ Hydrochlor., Sodii Arsenatis, and Trinitrini. Though these liquors are in reality 1 per cent. solutions, owing to the difference between the minim and the avoirdupois grain they contain 1 gr. of the active ingredient in 110 minims and not 1 gr. in 100 minims as the practitioner is too apt to imagine when dealing with 1 per cent. solutions. They are made by dissolving 1 gramme of the active ingredient in 100 cubic centimetres of solvent. The introduction of the metric system into the British Pharmacopœia does not appear to make the time of its final acceptance in this country any nearer. Practitioners stand in relation to it exactly where they did and it remains to be proved that this laudable intention of the revisers will popularise the new system with the dispensing chemist. Unquestionably the revisers should have gone much further or else left matters as they were. If they had wished to gradually accustom the prescriber to the use of metric weights and measures one way was open to them which they have not thought it desirable to follow. This was to give the dose of every substance and preparation in equivalents of the metric system in addition to the avoirdupois or imperial system. Mr. Martindale has, however, accomplished this in his last edition of the Extra Pharmacopœia with much labour and accuracy.

We would advise the practitioner to take a note of the following important *increases* in the strengths of preparations: Tinctures of belladonna, nux vomica, and podophyllum, 100 per cent.; tincture of quassia, about 270 per cent.; blistering liquid, 100 per cent. Discs of cocaine, and the tincture of chloroform and morphine are four times stronger; spirits of cajuput, cinnamon, peppermint, nutmeg, and rosemary are five times stronger; and pill of phosphorus is increased by 80 per cent. in strength. Of the notable *diminutions* in strengths he should specially note tincture of aconite, 60 per cent.; tincture of strophanthus, 50 per cent.; injections of apomorphine and of morphine, 50 per cent.; suppositories of morphine, 50 per cent.; alcoholic extract of belladonna, 66 per cent.; nux vomica, 33 per cent.; Calabar bean, 75 per cent.; liquid extract of opium, 25 per cent.; and chloroform water, 50 per cent. weaker.

The following important changes in the names of Galenical preparations should be carefully noted, otherwise serious mistakes may arise in prescribing and dispensing. The old Linimentum Iodi was prepared by dissolving 2½ oz. iodine and 1 oz. iodide of potassium and ½ oz. glycerin in 20 oz. rectified spirit. It is now called *Liquor* Iodi Fortis and has its composition slightly altered. It is made by dissolving 2½ oz. iodine and 1½ oz. iodide of potassium in 2½ oz. distilled water and 18 oz. 90 per cent. alcohol. The 1885 British Pharmacopœia Liquor Iodi was about one-third of the strength of this. It is now omitted, and notwithstanding the omission the revisers have thought proper to append the adjective *fortis* although there is now no weak iodine liquor official. It should be noted that it is about four and a half times the strength of the tincture. The omission of glycerin from its composition is a decided advantage. In the 1867 Pharmacopœia it was of about the same strength, but it contained camphor (½ oz. in 20 oz.); in the 1885 revision this was omitted and for some unknown reason glycerin was added. The present revisers have wisely omitted this and their action affords another example of how thoroughly they have reversed the decisions

[1] Articles I., II., III., IV., V., VI., and VII. were published in THE LANCET of April 16th and 23rd, May 7th and 28th, June 18th and 25th, and July 9th, 1898, respectively.

Digitized by Google

of the committee which was responsible for the preparation of the 1885 Pharmacopœia and the additions of 1890. The next British Pharmacopœia will probably see this Galenical again altered in its formula, as we suspect that it contains too much iodide of potassium.

Ergotinum of the 1885 Pharmacopœia was defined as "purified extract of ergot, commonly called Ergotin, Ergotine, or Bonjean's Ergotine." It is now called Extractum Ergotæ with the synonym Ergotin and appears in the new volume amongst the Extracts, and minute directions are given for its preparation from powdered ergot by treatment with alcohol, water, diluted hydrochloric acid, and sodium carbonate. The old dose was given as 2 to 5 gr., a quantity, in our opinion, large enough for all ordinary purposes; the new dose is stated as 2 to 8 gr. The old ergotin was simply prepared by evaporating the official liquid extract of ergot on a water-bath till it became of a syrupy consistence, when rectified spirit was added and after filtering, the evaporation was continued till the consistence of a soft extract was reached. It is just possible that the radical change made in the process of manufacture may justify the increase of the dosage. In consistency with the change in the nomenclature of ergotin the hypodermic injection is now altered to Injectio Ergotæ Hypodermica and its composition is changed by the addition of a small quantity of carbolic acid, and though its strength is slightly altered the dose remains as before—3 to 10 minims—though this dosage is altogether out of proportion less than that given for ergotin. Thus the maximum dose of ergotin in the injection is 3·3 grains (and this preparation is the one selected in urgent or desperate cases), whilst 8 grains may be given of the ergotin.

Linimentum Camphoræ Compositum is now to be known as Linimentum Camphoræ Ammoniatum with the old name retained as a synonym. Though it is not apparently intended by the revisers, its strength will be found to be appreciably increased, because in the old formula 2½ oz. camphor and 1 drachm oil of lavender were dissolved in 5 oz. strong solution of ammonia and 15 oz. rectified spirit. This solution made a liniment of about 1 in 9. In the new formula the same ingredients are used in the same quantities, only the spirit is added in sufficient amount to make the finished liniment measure only 20 fluid ounces, which represents a strength of 1 in 8 of camphor. A glance at the new formula will show one of the marked changes running through the volume—i.e., the omission of the absurd plan of "fluid parts" introduced into the 1885 Pharmacopœia; we are unfeignedly pleased at the omission. Pilula Asafœtidæ Composita is now to be known as Pilula Galbani Composita, with the remarkable official synonym "Compound Pill of Asafetida," *not* Pil. Asafetidæ Co. The nomenclature of the new British Pharmacopœia defies criticism or explanation the more we look into it. Thus, running all through the volume we have headings in full Latin whilst the English immediately underneath, though presumably a translation of the heading, is often anything but a literal translation, for example—Hydrargyri Iodidum Rubrum—Mercuric Iodide; Ferri Sulphas—Ferrous Sulphate, &c. Criticism is disarmed by the statement in the preface—viz., "It has been thought desirable to adopt certain well-established changes in chemical nomenclature, though not in such a manner as to occasion inconvenience to prescribers and dispensers. No general alteration, therefore, has been made in the Latin titles, but the English titles of chemical substances have in many instances been modified. These English titles therefore are not as a rule literal translations of the Latin ones." There was one plan open to the revisers by which this violation of custom and outrage upon a dead language might have been avoided—they might have given a literal translation of the title and in each case inserted their "well-established change in chemical nomenclature" as a *synonym*. The synonyms might with little objection have been employed throughout the body of the volume as in the formulæ and the various processes; this would have met every difficulty and obviated what has universally been regarded as a blot upon the literary aspect of the work.

There is still much confusion and real difficulty about one vital point—When does or when did the new British Pharmacopœia actually come into force? We find that no provision was made for this and some druggists still continue to dispense the prescriptions of practitioners by using the preparations of the old Pharmacopœia. Many druggists have sent out notices to the medical practitioners in their districts that on and after a certain date the new British Pharmacopœia will be used for all new recipes, but no uniform practice has been adopted. The licensing bodies and some of the universities have already issued printed information for intending candidates stating that all questions in the approaching autumn examinations in Materia Medica may be answered from the old Pharmacopœia. A sufficient time has now elapsed for every druggist to be supplied with the new Galenical preparations and we hold it to be incumbent upon every medical man to make himself familiar with the numerous changes and to write for some months to come upon his recipes either the words B.P. 1898 or B.P. 1885 after each preparation the strength of which is materially altered. In this way with little trouble errors may be entirely prevented. From what we have pointed out our readers will see that though there may be differences of opinion upon many points of detail in the revision of the British Pharmacopœia, we can only repeat what we have already stated—viz., that the revisers have made an honest and in the main a successful attempt to raise the standard of the work, and in conclusion we tender them the thanks of the medical profession for their labours.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE thirty-first sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, July 25th. With the exception of Sir George Barclay Bruce all the Commissioners were present. The whole of the sitting was occupied by the examination of Mr. Reginald E. Middleton, who appeared to give "expert evidence" on behalf of some of the water companies. At the commencement of the proceedings Mr. PEMBER, Q.C., on behalf of the Metropolitan Water Companies, asked the Chairman if he would examine the witness fully with regard to some of the details contained in the printed statement which he had put in. On behalf of the water companies Mr. Pember said that they wished to establish what he might term a "constructive case." The evidence now tendered and that which he proposed on behalf of his clients to bring forward at future sittings was intended not merely as a criticism of the case so ably brought forward by the London County Council. The water companies wished on their part to state what their own policy was if they were allowed to continue to supply their authorised area with water on the statutory conditions which at present existed. Amongst the points in the statement of Mr. Middleton to which he wished especially to call the attention of the Chairman and of the Commissioners were, in the first place, the estimate with regard to the probable increase of the population of "water London"; and, secondly, that they were of opinion that not only could 300,000,000 gallons of water be obtained daily from the Thames but that the river could supply a greater quantity should it be required; thirdly, it was part of the case of the metropolitan companies that the state of the Thames had improved with regard to purity. With regard to the quantity of water which could be derived from the Thames he contended that the present authorised supply of 185,500,000 gallons could without detriment to the river not only be increased to 300,000,000 gallons daily, but it seemed possible that not less than 400,000,000 gallons daily could be obtained should occasion require.

The CHAIRMAN proposed that Mr. Pember should examine the witness himself, but that counsel suggested that as in the case of the witnesses of the London County Council the examination-in-chief had been conducted by the Chairman and the Commissioners it might be better if the same course were adopted in the present case. The CHAIRMAN said that the mass of figures and the number of tables given in Mr. Middleton's statement were extremely puzzling, especially as some of the tables were not drawn up on the same lines as those which had previously been before the Commissioners. In the course of the proceedings which followed it may be here remarked that consecutive questions were occasionally asked by different Commissioners on different tables and the impressions as to the evidence given varied greatly, as may be learnt from a perusal of the reports which have appeared in the daily papers.

Mr. MIDDLETON was first examined by the Chairman with regard to the future population of London. The witness pointed out that Lord Balfour's Commission did not commit

Digitized by Google

themselves to any statement as to what the population would be in the year 1931: they had said that in their opinion it would be more than 11¼ millions. In the opinion of the witness the population would almost certainly be less than this, and if he were right in this conclusion the present sources of supply would amply provide a sufficiency of water for a longer period than that for which the estimate was made. A population of 5,732,950 in the year 1891, quoted in the report of Lord Balfour's Commission, was that for "Greater London" and exceeded the population supplied by the metropolitan companies at that date by over half a million. The present rate of increase in "water London" appeared to be about 15·53 per cent. per decennium. If this rate were adhered to the population in 1931 would be 9,274,046 and in 1937 10,164,349. The amount of water necessary for the supply of this population would be about 356,000,000 gallons daily, or 51,000,000 gallons in excess of the amount for which provision is now being made or construction authorised. With regard to the quantity of water which could be taken from the Thames the witness said that he was of opinion that an amount much in excess of 300,000,000 gallons daily could be obtained without injury to the river. The witness further said that he thought 400,000,000 gallons daily could be taken without injury.

In answer to Major-General SCOTT the witness said that in his opinion that amount could be taken without injury to other parts of the Thames basin.

In answer to Mr. PEMBER, Q.C., the witness said that that quantity could be taken without reducing the flow of the river below an amount of 200,000,000 gallons daily.

The Right Hon. J. W. MELLOR asked the witness whether he had taken any account of water which might be wanted by outside authorities. The witness replied that if the water were taken from wells it would not deplete the Thames and in answer to a further question from Mr. Mellor he said that the abstraction of water from wells would not in his opinion affect the flow of the Thames water.

The CHAIRMAN asked the witness whether the abstraction of the water from wells in the valley of the Lee affected the flow of that river. The witness, in reply, said that in isolated cases the abstraction of water from wells had diminished the flow of water in the river.

Mr. MELLOR asked the witness whether he had taken at all into his calculations the effect that might happen if water were required for the supply of a population situated in the higher parts of the Thames valley, and the witness replied that he had not taken it into calculation at all.

In answer to the CHAIRMAN the witness said that he did not believe that pumping from wells in the Lee valley had any sensible effect. The wells at Ware, which were situated on a bed of gravel, were sometimes pumped down. Three wells were slightly affected but they were not pumped dry.

The CHAIRMAN pointed out that the Commissioners had examined Sir John Evans, who had given evidence with regard to the wells in the Lee Valley, and that the witness had said "that the well at Haileybury College is pumped down." The witness said that he did not believe that statement.

The CHAIRMAN pointed out that they had had a witness before them who said that he could substantiate the statement and that Sir John Evans had also said that "the flow of the Ash, Rib, Quin, and Beane tributaries of the Lee had fallen off." The witness said that this statement was not correct.

Major-General SCOTT suggested that if pumping lowered the water in wells it would have an effect on the flow of a river.

Mr. PEMBER, Q.C., pointed out that the witness admitted that here and there such a thing might happen, "but in a general way no."

In answer to Sir JOHN DORINGTON the witness said that he had heard the evidence which Sir John Evans had given to the Royal Commissioners and that the inferences which had been made from evidence which the witness had given before the Balfour Commission were not correct. With regard to the reservoirs recommended by Lord Balfour's Commission the witness pointed out that the Commissioners did not express any "insistence on Staines" as a locality, they had expressed their approval of reservoirs situated in the Thames Valley as near the intakes of the companies as possible. When Messrs. Hunter and Fraser arranged for intakes to be above Bell Weir, Staines, Sunbury, and some other places drained into cesspools. At the present time many of these places have constructed sewage disposal works.

With regard to the state of the Thames water the witness in his statement quoted the report of Sir E. Frankland as to the quantity of organic matter found in the Thames water as supplied to consumers.

Major-General SCOTT pointed out that the quality of water as supplied to consumers differed from the Thames water before filtration and that therefore the evidence which the witness put in on that point did not bear the interpretation which the witness suggested—namely, that the river itself was purer. With regard to the purity of the water in the River Thames Major-General Scott asked the witness on how many analyses the report was founded. He suggested that they were very few in number and asked the witness how he could suggest that any definite knowledge could be derived from such a small number of analyses.

Mr. MELLOR asked the witness whether he considered that the amount of organic impurity of the present Thames water was bad and the witness immediately replied, "Oh, no."

Major-General SCOTT suggested that the experiments made were haphazard and asked whether the witness seriously contended that any conclusions could be founded on them.

The CHAIRMAN pointed out that he would not like to draw any conclusions from these "fluctuating figures." What conclusion did the witness wish they should arrive at?

Major-General SCOTT insisted that the evidence was founded on very slender foundation and that no certainty could be arrived at with regard to the present as compared with the past condition of the Thames. With regard to the possible amount of water which could be obtained from the county of Kent Major-General Scott asked the witness whether he had made any investigations since the date of the Balfour Commission Report, from which he quoted. The witness said that he had not made any observations and Major-General SCOTT remarked that they, the Commissioners, could refer to the Balfour Report for themselves, and that they had had witnesses who had given evidence with regard to the present state of the water in the Kent district. The witness suggested that in his opinion wells sunk in the chalk in the basin of the Thames could, if necessary, supply a quantity of 190,000,000 gallons daily. Major-General Scott pointed out that this was quite contrary to the opinion expressed by the Balfour Commission. The witness did not give any evidence in favour of his opinion that 190,000,000 gallons daily could be supplied from wells in the chalk but said that he had made many journeys up and down the Thames, had studied the readings of the rain-gauge and had made observations with regard to the percolation of water. With regard to the storage of water the witness pointed out that at the present time the metropolitan companies were not obliged to store water in reservoirs and that they were authorised to take a considerable quantity of water and distribute it without storage. This, the CHAIRMAN remarked, "was not altogether pleasant for consumers."

After the adjournment for luncheon the witness gave evidence with regard to the cost of the Welsh scheme and gave figures which did not agree with those which had been given by Sir Alexander Binnie. The figures will be best understood by a study of the tables drawn up by Mr. Middleton, which we append. With regard to the method by which Mr. Middleton had arrived at some of his estimates the witness said that some of them were made from "analogy."

MR. MIDDLETON'S TABLE SHOWING COMPARATIVE COST OF SUPPLYING 114½ OR 123½ MILLION GALLONS FROM WALES AS ESTIMATED BY SIR ALEXANDER BINNIE AND BY HIMSELF.

SIR A. BINNIE.

Cost of obtaining by the Welsh gravitation scheme the 114½ millons, being the difference between the total 300 million gallons of the Staines scheme and the 185½ million gallons sanctioned taking of water from the Thames by the companies up to date.

	£
Yrfon yield, 121 million gallons per day—Yrfon reservoir and head works	1,850,000
Aqueduct.—162 miles in length, composed of 117 miles of covered conduit and tunnel, to carry 200 million gallons a day, and 45 miles of pipe, to carry 114 million gallons a day	6,867,500
Terminal works at Elstree for 114 million gallons a day, exclusive of filters	1,314,750
	£10,032,250

This estimate is equivalent to that the total of which, as given by Mr. Deacon was £9,848,000, but Mr. Deacon made a proportionate reduction in the cost of the masonry and tunnel portion of the conduit to reduce it to the flo w of 133½ million gallons a day, whereas I have

Digitized by Google

preferred to make those portions of the full size for 200 millons gallons a day in the first instance, as I have always based my calculations on the assumption that the Welsh project will be carried out in instalments as necessity may require. Note should be also made of the saving in pumping pointed out by Mr. Deacon in his estimate.

MR. MIDDLETON.

Cost of bringing 123½ million gallons from Wales to London calculated by analogy from the cost of the Thirlmere, Vrynwy, and Elan Valley works.

YRFON RESERVOIR.

	£
Cost of storage for the delivery of 123½ million gallons daily and for 81 miles of pipe-lines and conduit at an average cost of £91,611 per million gallons of daily supply	11,313,958
Cost of an average of 81 miles of conduit beyond that in the Thirlmere, Vyrnwy, and Elan Valley schemes to convey 215 million gallons daily at £64,000 per mile ...	5,184,000
Terminal works at Elstree	1,314,750
	£17,812,708
Add for mains between service reservoirs at Elstree and the service reservoirs of the companies	3,000,000
Add cost of pumping machinery to pump to supply 30 million gallons daily to the districts above gravitation level, equal to 2184 p.h.p. at £45 per p.h.p. ...	98,280
Total capital cost	£20,910,988
Add cost of pumping to supply the districts above gravitation level during 20 years a quantity increasing from 21·7 to 29·8 million gallons, at 30*s.* per million gallons pumped...	279,549
	£21,190,537
Add for accumulated interest	13,078,046
	£34,268,583

N.B.—If pumping charges are capitalised at 30 years' purchase a sum of £253,746 must be added, making the total £34,522,329.

Notes of difference.—Mr. Middleton's first two items—£11,313,958 and £5,184,000, total £16,497,958—approximately correspond with Sir A. Binnie's two items of £1,850,000 and £6,867,500, total £8,717,500. Sir A. Binnie has, however, included no estimate for cost of mains, pumping machinery, pumping charges, and interest. Mr. Middleton has estimated for a conduit as to 81 miles capable of carrying 123½ million gallons and as to the remaining 81 miles capable of carrying 215 million gallons per day, the total yield of the first group of Welsh reservoirs.

MR. MIDDLETON'S TABLE OF COMPARISON OF SIR A. BINNIE'S AND HIS OWN ESTIMATES OF COST OF SUPPLYING FROM THE THAMES 114½ MILLION GALLONS PER DAY, IN ADDITION TO THE TAKE OF 185½ MILLION GALLONS PER DAY ALREADY AUTHORISED, MAKING A TOTAL OF 300 MILLION GALLONS PER DAY.

SIR A. BINNIE.

	£
Capacity for 114½ millions, 20,000 million gallons... ...	6,785,980
* Pumping into Reservoirs, 19,717 at 5*s.* per million gallons = £4929. Capitalised at 30 years	147,870
† Cost of pumping to supply 114½ million gallons per day = 41,792½ at £2 10*s.* per million gallons = £104,481. Capitalised at 30 years	3,134,430
	£10,068,280
Pumping machinery for distribution, reckoned on the capital sum of £1,212,300, apparently included as a total in 1941 for this purpose in the estimate of Messrs. Hunter and Fraser	816,525
	£10,884,805

* The charges for pumping to store have been capitalised on the draft during the year of greatest drought, not on the average of years as they should have been.

† This capitalisation has been made on the cost of pumping 114½ million gallons per day, which will not be reached until the year 1935; it should be, on the average, less than half that quantity. The sum so arrived at should be discounted for present value.

MR. MIDDLETON.

	£
Capacity, 14,987 + 10 per cent. = 16,486 million gallons, at £218 per million	3,593,948
* Pumping into reservoirs 10,570 million gallons, average for 19 years at 7*s.* 6*d.* per million gallons = £3963 15*s.* For 19 years	75,316
* Cost of pumping to supply a quantity increasing from *nil* to 114½ million gallons per day during 19 years at £2·41 per million gallons	932,536
	£4,601,800
Pumping machinery for distribution	375,480
	£4,977,280
Note.—A sum of about £500,000 should be added to this estimate for connecting mains to the boundaries of the companies' districts, to compare with the item of £3,000,000 for connecting mains between the service reservoirs at Elstree and those of the companies in the Welsh scheme	500,000
Total	£5,477,280
* If the pumping charges be capitalised at 30 years' purchase a sum approximating to £1,682,580 must be added. (This has been done by Sir A. Binnie, but I do not concur)	1,682,580
	£7,159,860

Major-General SCOTT pointed out that the figures put in by Sir Alexander Binnie were the result of observations made on surveying the site of the proposed work. Sir Alexander Binnie's estimate for the Welsh scheme had been compared by the witness with the costs of the Thirlmere and Vyrnwy supplies and with the estimated cost of that from Elan Valley supply, and judging from the amount paid in those cases the witness said that he believed that the cost of providing 123,500,000 gallons of water from Wales in addition to the existing supply would cost a sum of about £21,000,000. On the other hand, he thought that the cost of the Thames reservoirs storage scheme to supply the same amount of water would be little over £5,000,000. To this sum of £5,000,000 must be added a further sum of £500,000 for the necessary arrangements for the conveyance of water from the Thames stations to the consumers. If an additional supply of water were derived from Wales the cost would be £22,640,800 for a supply of 135,000,000 gallons. For 172,000,000 gallons the cost would be £28,205,050, and for 215,000,000 gallons the cost would be £33,297,251.

With regard to the distribution of water from the reservoirs, which, according to the Welsh scheme, the County Council proposed to have at Elstree, the witness showed a plan of the distributing mains which he suggested should be made and gave a list of the existing service reservoirs which could be filled from Elstree by gravitation and a list of those which could not be economically filled from Elstree without the use of pumps. These tables gave in each case the top-water level of the reservoirs and their capacity. As these facts have been already given in THE LANCET it is not necessary to repeat them here, and therefore only the list of reservoirs is given, arranged in the two categories mentioned.

List of existing Service Reservoirs which could be filled from the proposed Service Reservoirs at Elstree by Gravitation.

Chelsea Company—Putney Heath.
East London Company—Woodford, Hornsey Rise.
Grand Junction Company—Campden-hill, Hanger-hill, Ealing.
Kent Company—New Cross, Plumstead Common, Greenwich Park, Dartford, Deptford.
Lambeth Company—Brixton, Streatham, Combe.
New River Company—Claremont-square, Maiden-lane, Crouch-hill, Bourne-hill.
Southwark and Vauxhall Company—Nunhead.
Middlesex Company—Campden Hill, Barrow Hill, Willesden.

List of existing Service Reservoirs which could not be economically filled from the proposed Service Reservoirs at Elstree without the use of Pumps.

East London Company—High Beech, Buckhurst Hill.
Kent Company—Woolwich Common, Chislehurst, Shooter's Hill, Farnborough (Cowlass Hill), West Wickham, Knockholt, Betsom's Hill, Westerham, Eltham.
Lambeth Company—Selhurst, Rockhills, Norwood.
New River Company—Hornsey-lane, Highgate, Hampstead, Southgate, Bush Hill, Enfield.
Southwark and Vauxhall Company—Forest Hill.
Middlesex Company—Kidderpore, Shootup Hill.

Towards the end of the sitting the CHAIRMAN asked Mr. Pember how much time the evidence submitted by the water companies would be likely to occupy, and Mr. PEMBER said that their case might be disposed of in about ten sittings. The case for the London County Council had been very fully stated and it was the wish of the companies to state with equal fulness their view of the situation.

At the conclusion of the sitting the Commissioners adjourned until November.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE summer general meeting of the above association was held on Wednesday, July 27th, at 2 P.M., in the students' reading room, Edinburgh.

In the absence of the President (Dr. MAPOTHER), who was detained in London, the chair was occupied by Dr. RICHARD HEATH (St. Leonard's-on-Sea.)

The CHAIRMAN said he was glad to see such a good muster of members notwithstanding the many attractions of the hospitable citizens of the "Northern Athens." He called upon the provincial honorary secretary to make a statement in reference to the hospital appointments question.

Mr. J. STEWART said that since their last provincial meeting another English hospital—and he was glad to say it was a metropolitan one—had rescinded the rule which had previously prevented anyone but a Fellow of the English College of Surgeons from holding a position on the

Digitized by Google

honorary surgical staff. He alluded to St. Peter's Hospital for Stone, Covent-garden. These strongholds of monopoly were gradually being reduced in number and he (Mr. Stewart) felt sure that the innate sense of justice which was so marked an element in the English character would ere long lead the governors of the remaining hospitals where the exclusive rule prevailed to open their doors to fully-qualified candidates holding the higher diplomas obtained by examination no matter in which division such diplomas had been obtained. The victories which the association had already gained at Bristol, St. Leonard's-on-Sea, Brighton, and other places were an earnest of what was before them if all those holding Irish diplomas would give a helping hand by joining the association, the membership of which now numbered nearly 750, but which ought to be over 1000.

The CHAIRMAN announced his intention of giving a donation of £10 to the Hospitals Disabilities Fund on the understanding that one of the monopoly strongholds, such as Liverpool, should be attacked by the council as soon as possible and he concluded by moving—

That this meeting hereby records its regret that so many English public hospitals have still among their regulations a rule the effect of which is practically to exclude from candidature for honorary appointments on the staff all who do not hold the diplomas of two specially favoured London colleges.

Dr. P. S. ABRAHAM proposed a vote of thanks to Mr. Stewart for his address and for the untiring efforts he had made for years to bring the monopoly question before the profession and the public.

This was seconded by Mr. JOCELYN SWAN and carried with acclamation.

A vote of thanks to the Chairman concluded the proceedings.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

THE Secretary of State has made the following further appointments of medical referees under the Workmen's Compensation Act, 1897:—

Circuit No. 3.—Dr. Roderick Maclaren and Dr. Henry Ambrose Lediard, Carlisle; Dr. George Bertram Muriel, Whitehaven; and Dr. Archibald Carmichael, Barrow-in-Furness.

Circuit No. 6 (revised list).—Mr. George Gibson Hamilton, Dr. Thomas Clarke, and Mr. Charles Stuart Pethick, Liverpool; and Mr. Robert Meredith Littler, Southport.

Circuit No. 9.—Mr. William Hugh Hughes, Ashton-under-Lyne; Dr. James Thomson Wilson Baird, Congleton; and Mr. Thomas Castley Bailey, Crewe.

Circuit No. 15.—Mr. Samuel Walker, Middlesbrough; Dr. Charles Dennis Hill Drury and Dr. Walter Petter, Darlington; Mr. Henry Hind, Harrogate; and Mr. William John Beatty, Stockton-on-Tees.

Circuit No. 18.—Dr. Ernest Stanley Nutting, Warsop; Dr. Henry Handford and Mr. Alexander Richard Anderson, Nottingham; and Mr. Simeon Snell, Sheffield.

Circuit No. 19.—Dr. Edmund Vaudrey and Mr. William Legge, Derby.

Circuit No. 22.—Dr. Frederic Thorne, Leamington Spa; Dr. Clement Dukes and Dr. Alfred Russell Darley, Rugby; Mr. Frank Faulder White, Coventry; and Mr. George Heaton, Birmingham.

Circuit No. 24 (further appointment).—Mr. Edward Treharne, Barry.

Circuit No. 26.—Mr. William Dunnet Spanton, Hanley; Mr. George Stokes Hatton, Newcastle-under-Lyme; and Dr. John Holmes Joy, Tamworth.

Circuit No. 27.—Dr. Paul Morgan Chapman, Hereford; and Mr. William Alma Aylmer Lewis, Oswestry.

Circuit No. 29.—Mr. Farington Marsden Granger, Chester; Dr. Joseph Llewelyn Williams, Wrexham; Dr. John Lloyd-Roberts, Denbigh; Mr. John Williams, Carnarvon; and Dr. Edward James Lloyd, Bangor.

Circuit No. 31 (additional appointment).—Dr. Frederick Robson, Port Talbot.

Circuit No. 36.—Dr. Frank Buszard and Mr. Robert Arthur Milligan, Northampton; and Mr. Horatio Symonds and Dr. William Collier, Oxford.

Circuit No. 38.—Dr. Robert James Banning, Shoeburyness; Mr. Murtaugh James Houghton, York-road, Ilford; and Dr. Edward Liveing Fenn, Colchester.

Circuit No. 44.—Dr. John George Garson, 64, Harley-street, W.; Dr. Fletcher Beach, 64, Welbeck-street, W.; and Dr. George Washington Isaac, 75, Gower-street, W.C.

Circuit No. 47.—Mr. Francis James Steward, 24, St. Thomas-street, London Bridge, S.E.

Circuit No. 51.—Dr. William Sykes, Gosport; Dr. John Ward Cousins, Southsea; Mr. Wilfred Balgarnie, Winchfield; and Mr. Ernest Frederick Elliot, Southampton.

Circuit No. 52.—Mr. Frederick King Green, Bath.

Circuit No. 57.—Mr. Joseph Harper, Barnstaple; and Dr. George Lorraine Kerr Pringle, Bridgwater.

Circuit No. 59.—Dr. Peter Gardiner, Camborne; Dr. Arthur Edward Permewan, Redruth; Dr. Hugh Culliford Sharp, Truro; and Mr. Joseph William Gill, Liskeard.

THE ARMY MEDICAL SCHOOL.

THE seventy-sixth session of the Army Medical School, Netley, was brought to a close on July 29th, when the prizes were presented to the successful officers by Lord Lister, in the presence of a large company which included Surgeon-General Jameson, C.B., Director-General of the Army Medical Department; Sir Joseph Fayrer, Bart., K.C.S.I.; Deputy-Surgeon-General Cayley; Surgeon-General M. Webb; the officers of the Army Medical School, and the military and nursing staff of the Royal Victoria Hospital.

The following lists give the positions of the young officers of the Royal Army Medical Corps and Indian Medical Service when leaving Netley, with the combined marks of the Netley and London examinations, the final positions on the lists being determined by the results of both examinations, while the prizes are awarded for marks gained in the special subjects taught at the school.

* Gained the Herbert Prize of £20, the Montefiore Second Prize in Surgery, the Martin Memorial Medal, and the de Chaumont Prize in Hygiene.
† Gained the Parkes' Memorial Medal.
‡ Gained the Montefiore Medal and Prize of 20 guineas.
§ Gained the Maclean Prize for Clinical and Ward Work.
‖ Gained the Pathology Prize presented by Sir Joseph Fayrer, Bart., K.C.S.I.

A report of the results of the examination was read by Lieutenant-Colonel J. L. NOTTER, Professor of Hygiene, who invited his lordship to distribute the prizes. After saying a few words to each successful officer Lord LISTER addressed the company and the young officers leaving the school. He said a remark had often been made on occasions like the present, and it was not stale; that was that those who had failed were also to be congratulated not because of their failure, because in many cases that had probably been an accident; but because although some persons had obtained a few more marks and had gained the actual nominal prize, the real prize had been gained by all of them who had striven to attain success. They had gained knowledge which would be a life-long possession to them, and he doubted not would prove of the greatest value to them in their after career. He congratulated the prize-winners on their success and all the young officers upon the fact that they were entering Her Majesty's services under better auspices than their predecessors had done. This was due to the wisdom and understanding shown by Lord Lansdowne, the Secretary of State for War, owing to whose liberal policy the slur which had been attached to the medical service of the Army had been completely removed, and he could not doubt that this would conduce to greater amenities in this branch of the service in the future and to greater self-respect. Whatever the general public might consider thinking men were well aware that their profession was a nobler one than that of arms. It was more exalted in its objects and gave greater scope for the exercise of the highest intellectual powers and the greatest virtues. The virtue which induced a man to tend from day to day his fellow man in the earnest endeavour to diminish the miseries which accident and disease occasioned was one in which their noble profession was especially conspicuous. He considered that the heroism of the medical officer who calmly did his duty on the battle-field was of a higher order than that shown by the combatant who did brave acts

Digitized by Google

inspired by the excitement of battle, and he reminded the young officers that in times of peace, when the combatants were largely engaged in the somewhat tedious duties of drill, they themselves would be ever occupied in observing the variations of disease and in making inquiries whereby they would often have opportunities of advancing medical science. As an example of the quiet bravery shown by a medical officer Lord Lister recalled the work done by Sir Joseph Fayrer at Lucknow when exposed constantly to the greatest peril. Continuing his short address his lordship adjured the young officers to keep in view the nobility of their calling. He congratulated them upon the knowledge they had acquired in the great school they were leaving, upon the bright prospects before them, and above all upon being about to enter on the active practice of a profession the due performance of which brought its own never-failing great reward.

The DIRECTOR-GENERAL, in asking the company to accord Lord Lister a very hearty welcome to Netley, said that his visit was especially interesting to them because of his lordship's great services to the world in general and to the army in connexion with aseptic surgery. He mentioned that during the late frontier war in India no death had been due to a wound becoming septic and that all the nine cases of compound fracture of the thigh did well and that we owed these results to Lord Lister's great discoveries and work. He said that among both officers and men a feeling still lingered that the oftener their wounds were dressed the better it would be for them, and that there were those who gauged the attention shown to them by the frequency of wound dressing, while the fact was that if wounds were treated on the principles which Lord Lister had introduced the less a wound were touched after the first dressing the better—that, in fact, wounds should not be redressed for eight or ten days. He hoped that Lord Lister's visit would do something to spread these truths among the officers and soldiers of the army and remove prejudice from the mind concerning a system of treatment which the whole medical profession regarded as scientific. He asked the audience to extend to Lord Lister a very hearty welcome on his visit to Netley.

Sir JOSEPH FAYRER added a few words of congratulation to the successful officers and said that although his official connexion with the school had long ceased it was a source of pleasure to him to watch its progress and to see the results which the Netley teaching had achieved both in India and in other parts of the world. He hoped that the knowledge which they had gained would suggest further investigations, for there was still a great deal lying open to discovery, and he urged and advised them to do their best so that they might thereby become great benefactors to their profession and to the army. In conclusion he congratulated them upon the new titles which Lord Lansdowne had conferred upon them, remarking that in the army only one set of titles carried any weight and enabled men to carry out their duties properly; these titles had now been granted to them and would, he felt sure, be used by them to carry out their responsible duties as the medical officers of the army effectively. No medical officer wanted to command regiments, but as they had other duties to perform it was necessary that they should have military authority and control.

Surgeon-General NASH, Principal Medical Officer of Netley, said he had now to close the session of the school. He hoped that those leaving Netley would feel that their stay there had been profitable and that they would look back upon the time spent in the school as a pleasant one. He wished them success in the services to which they belonged and in which they that day became officers.

Lord Lister and the company were subsequently entertained at luncheon by the officers of the Royal Army Medical Corps.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held on Wednesday, Aug. 3rd, at the Mansion House, to receive the report of the Committee of Distribution and to order payment of awards to hospitals and dispensaries as well as for the transaction of general business. In the absence of the Right Hon. the Lord Mayor, the chair was taken by Sir SYDNEY WATERLOW, Vice-president of the Fund.

The report stated that the Committee of Distribution recommend awards this year to 186 institutions, being an increase of 81 since the first awards were made in 1873 and 2 less than last year. The total amount available for distribution, after allowing for liabilities and the usual current expenses, is £35,000. Of this total £34,304 is now recommended to be paid to 132 hospitals and 54 dispensaries. This year 195 institutions have made applications for grants from the fund. Of this number it was found necessary to invite the attendance of deputations from the governing bodies of 17. In 6 of these cases, including two applications which were withdrawn, the committee were not able to make any recommendation. Deputations from twelve hospitals and from one dispensary conferred with the committee and in nearly every case the committee received explanations modifying the causes of adverse criticism and enabling them to raise the bases of awards as now recommended. Arrangements for restricting the advantages of the out-patient system to the poor have been made at nearly all the large and at some of the smaller hospitals. The practice of making a small charge to out-patients is rather on the increase. The amount available for distribution is less than that distributed last year, but the committee feel that following on a Jubilee year in which strong appeals were made in other directions, the collections this year on Hospital Sunday maintain a fair average, and that the confidence of the public in the Metropolitan Hospital Sunday Fund is well sustained.

Previously to the consideration of the report the CHAIRMAN announced that Mr. Ludwig Mond had for the eleventh time given his annual subscription of £100.

In moving the adoption of the annual report for the twenty sixth time Sir SYDNEY H. WATERLOW said that he could congratulate the fund on the amount collected this year, though the sum was smaller than in previous years. Up to date £38,741 12*s.* 6*d.* had been received and when the difficulties under which collections were made in 1898 as compared with former years were remembered there was very much reason, he thought, to be thankful to ministers of all denominations who had succeeded in collecting so large a sum. Many of their large contributors had either transferred their subscriptions to the Prince of Wales's Fund or had divided their contributions. Referring to hospital abuse he said he believed that it did not exist to any large extent, and the hospitals were doing what they could to check it by appointing officers to inquire into the merits of patients. Sir Sydney Waterlow concluding by moving:—

That the report of the Committee of Distribution for the year 1898 be and is hereby approved, and that the several awards recommended be paid as soon as possible.

Dr. J. G. GLOVER, who seconded the adoption of the report, said he could not suppress his disappointment at the fact that there were £5000 less to distribute than last year.

The Hon. SYDNEY HOLLAND, supporting the motion, pleaded for more support from the public. Hospital managers who devoted their time to the management of hospitals ought to be relieved of the disagreeable work of begging, and he asked the press to make it known that unless the public supported hospitals more energetically than they did at present very evil times were in front of us.

The motion before the meeting was then passed unanimously.

Lord STAMFORD proposed:—

That the cordial thanks of the Council be and are hereby given to Sir Sydney H. Waterlow, Bart. (chairman), and to the other members of the Committee of Distribution for the discretion which they have exercised in interviewing numerous deputations and for the care bestowed in the preparation of the awards they have recommended.

Canon FLEMING seconded the motion, which was adopted.

Sir EDMUND HAY CURRIE proposed:—

That the thanks of the council be and are hereby given to the editors of newspapers who have pleaded the needs of hospitals and advocated the cause of this fund.

In seconding this Sir HENRY BURDETT suggested that greater prominence should be given to the fund by supplying editors of newspapers with literature relating to the fund from time to time and especially just before Hospital Sunday.

Sir SYDNEY WATERLOW said the matter of increased advertising was under consideration.

The resolution was carried.

Sir SYDNEY WATERLOW, in proposing a vote of thanks to

Digitized by Google

the Lord Mayor, which was unanimously adopted, referred to the advantage the fund received from having its home at the Mansion House.

Dr. GLOVER asked to be allowed to propose a motion to the effect that the Distribution Committee be requested to investigate and consider the cause of the diminution in the amount collected this year, and to report to the Council at the next meeting.

Mr. THOMAS CHRISTY seconded.

Sir H. BURDETT said he was in a position to state that with the exception of four hospitals, where the circumstances were special and the reasons apparent, every hospital in London last year had a more prosperous year than before. Whatever might be the cause of the fall in the amount collected for the Hospital Sunday Fund it was certainly not due to the year of the Queen's Diamond Jubilee or to the Prince of Wales's Hospital Fund.

Sir SYDNEY WATERLOW said that it would be invidious to make any comparison between the two funds.

Dr. GLOVER disclaimed the slightest wish to make any reflections on the Prince of Wales's Fund.

On the matter being put to the vote three members of Council voted for the motion and three against.

The proceedings then terminated.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE ordinary Comitia of the Fellows of the Royal College of Physicians of London was held on July 28th, the President, Sir SAMUEL WILKS, Bart., being in the chair.

It was announced that the Gulstonian Lectures for 1899 would be delivered by Dr. G. R. Murray, who had chosen the Pathology of the Thyroid Gland for his subject. The Croonian Lectures will be given by Dr. F. W. Mott.

The PRESIDENT stated that the Bradshawe Lecture would be given by Dr. Ord on Myxœdema and Allied Conditions.

Dr. W. B. Ransom was admitted to the Fellowship.

Edward Hanly, M.D. R.U.I., William Darley Hartley, M.D.Durh., and Edward Arthur Saunders, M.A., M.B.Oxon., were admitted Members of the College.

Licences were granted to 135 gentlemen who had passed the recent examination.

Dr. NORMAN MOORE, on behalf of a committee of the Fellows, presented to the College a portrait of Dr. W. Munk, the Harveian librarian, which had been painted by the Hon. John Collier. Dr. Moore recounted the services which Dr. Munk had rendered to the College and in particular dwelt upon his great work of the Roll of the College, which was first published in 1861, and of which a second edition appeared in 1878.—The PRESIDENT briefly acknowledged the gift in the name of the College.

A letter was read from the Charity Commission relative to certain proposals for the future care and maintenance of the Physic Garden at Chelsea, which had been, since its formation by Sir Hans Sloane, in the keeping of the Apothecaries Society, and it was resolved that the College should intimate its desire to be represented on any board of trustees which may be formed to take over the charge of the garden.

Communications were read from the secretary of the Royal College of Surgeons of England reporting the proceedings of its Council.

A letter was read from the Master of St. Katharine's Hospital inviting the College to nominate a representative to act on the council of the Queen Victoria Jubilee Institute of Nurses and in compliance with this request Sir Dyce Duckworth was nominated.

An application from the chairman of Charing-cross Hospital asking for the assistance of the College to the funds of the hospital was read, but the request could not be acceded to as the College had no funds at its disposal for such a purpose.

An application from Sir W. Turner on behalf of the family of the late Sir George Burrows for permission to have a replica made of the bust in the possession of the College to be presented to the General Medical Council was, after some discussion, granted.

The PRESIDENT having informed the College that the University of London Commission Bill had passed the third reading in the Commons a cordial vote of thanks was, on the motion of Dr. STEPHEN MACKENZIE, seconded by Dr. PYE-SMITH, awarded to Dr. Allchin for his long and arduous labours on behalf of the College in connexion with the University question.

On the motion of Dr. DICKINSON, seconded by Dr. CHURCH, it was unanimously resolved:—

The Royal College of Physicians having learnt that certain change are likely to be made in the laws relating to vaccination think it their duty to reiterate their conviction that vaccination, properly performed and duly repeated, is the only known preventive of small-pox, and this opinion they consider to be fully confirmed by the report of the present Commission.

It was further resolved that copies of this resolution should be communicated to Lord Salisbury, Mr. Arthur Balfour, Mr. Chaplin, and the journals.

The Censors and other officers, members of committees, and examiners for the ensuing year were then elected. (See appended list.)

An elaborate report was received from Dr. SIMS WOODHEAD upon specimens of Uganda arrow-head poison, which had been sent to the College from the Foreign Office. A copy of the report was directed to be sent to the Foreign Office and the thanks of the College were voted to Dr. Woodhead.

Reports from the Committee of Management and the Laboratories Committee were read and also reports from the representative of the College on the General Medical Council and from Dr. C. T. Williams, the representative of the College on the Council of Mason College, Birmingham, the latter detailing the proceedings of the meeting lately held to promote the establishment of a midland university.

Reports from the Finance, Museum, and Library Committees and from the examiners for the Licence were also presented.

The following is the list of officers and examiners who were appointed at the meeting:—Censors: Dr. Walter Butler Cheadle, Dr. William Miller Ord, Dr. Philip John Hensley, and Sir R. Douglas Powell, Bart., M.D. Lond. Treasurer: Sir Dyce Duckworth, M.D. Edin. Emeritus Registrar: Sir Henry Pitman, M.D. Cantab. Registrar: Dr. Edward Liveing. Harveian librarian: Dr. William Munk. Elected members of the Library Committee: Dr. Samuel Jones Gee, Dr. Philip Henry Pye-Smith, Dr. John Cavafy, and Dr. George Vivian Poore. Curators of the Museum: Dr. William Howship Dickinson, Dr. Henry Charlton Bastian, Dr. William Cayley, and Dr. Norman Moore. Finance Committee: Dr. Alfred Baynard Duffin, Dr. George Vivian Poore, and Dr. John Mitchell Bruce. *Examiners:* Chemistry and Chemical Physics: Dr. William Ramsay, F.R.S., Mr. Percy Faraday Frankland, Ph D., F.R.S., Mr. John Millar Thomson, F.C.S., Mr. Frederick Daniel Chattaway, Ph.D., and Mr. Henry Wilson Hake, Ph.D. Materia Medica and Pharmacy: Dr. Francis Warner, Dr. William Carter, Dr. Nestor Isidor Charles Tirard, Dr. Hector William Gavin Mackenzie, and Dr. James Calvert. Physiology: Dr. William Dobinson Halliburton, Dr. John Wychenford Washbourn, and Dr. Marcus Seymour Pembrey. Anatomy: Mr. George Robertson Turner and Mr. George Dancer Thane. Medical Anatomy and Principles and Practice of Medicine: Dr. William Cayley, Dr. Joseph Frank Payne, Dr. Thomas Henry Green, Dr. Thomas Lauder Brunton, Dr. Arthur Ernest Sansom, Dr. Horatio Bryan Donkin, Dr. Thomas Barlow, Dr. David Bridge Lees, Dr. Julius Dreschfeld, and Dr. William Hale White. Midwifery and Diseases peculiar to Women: Dr. John Baptiste Potter, Dr. Charles James Cullingworth, Dr. John Phillips, Dr. C. Montagu Handfield-Jones, and Dr. Robert Boxall. Surgical Anatomy and Principles and Practice of Surgery: Mr. John Langton and Mr. John Neville Colley Davies-Colley. Public Health: Part I., Lieutenant-Colonel James Lane Notter, M.D., R.A.M.C.; and Part II., Dr. William Henry Corfield.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Aug. 2nd the President, Sir WILLIAM MAC CORMAC, Bart., being in the chair.

The SECRETARY laid before the Council the balance-sheet and the certificates of the auditors, Messrs. Cooper Brothers and Co., certifying to the accuracy of the accounts for the past year. The balance-sheet and statement of receipts and expenditure were approved and adopted.

The Council considered the desirability of addressing a

Digitized by Google

protest to the Government in reference to the proposed alteration of the Vaccination Acts and it was decided to send the following resolution to the Government:

That in view of the proposed alteration in the laws relating to vaccination now contemplated in the Bill before Parliament the Council do reaffirm the following resolution adopted by them on May 11th, 1893, and presented to the Royal Commission on Vaccination, as expressive of their opinion on the value of vaccination—namely:—

We, the Council of the Royal College of Surgeons of England, desire to put on record at the present time our opinion of the value of vaccination as a protection against small-pox.

We consider the evidence in favour of its life-saving power to be overwhelming and we believe, from evidence equally strong, that the dangers incidental to the operation, when properly performed, are infinitesimal.

Experience has satisfied us that even when vaccination fails to afford complete exemption from small-pox it so modifies the severity of the disease as not only to greatly reduce its mortality but to lessen the frequency of blindness, disfigurement, and other grave injuries.

We should therefore regard as a national calamity any alteration in the law which now makes vaccination compulsory.

We are, moreover, firmly convinced that revaccination is an additional safeguard and should be universally practised.

We would add that we believe that the instructions of the Local Government Board for public vaccinators are well designed to secure the greatest efficiency in vaccination and to avoid the liability to risks from the operation.

A letter was read from Mrs. Lee thanking the Council for their condolence on the death of her husband, Mr. Henry Lee.

A letter was read from the Registrar of the General Medical Council forwarding copies of the recommendations of that Council respecting dental education and examination. The subject was referred to the Board of Examiners in Dental Surgery to consider and report.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6910 births and 3709 deaths were registered during the week ending July 30th. The annual rate of mortality in these towns, which had been 14·7 and 15·6 per 1000 in the two preceding weeks, rose further last week to 17·2. In London the rate was 16·8 per 1000, while it averaged 17·5 in the thirty-two provincial towns. The lowest rates in these towns were 9·4 in Cardiff, 11·0 in Blackburn, 11·2 in Preston, and 11·9 in Brighton and in Burnley; the highest rates were 23·0 in Liverpool, 23·7 in Halifax, 25·3 in Birkenhead, and 27·3 in Salford. The 3709 deaths in these towns included 572 which were referred to the principal zymotic diseases, against 378 and 487 in the two preceding weeks; of these, 356 resulted from diarrhœa, 62 from measles, 61 from whooping-cough, 47 from diphtheria, 29 from "fever" (principally enteric), and 17 from scarlet fever. No death from any of these diseases occurred last week in Bolton; in the other towns they caused the lowest death-rates in Bradford, Hull, and Oldham, and the highest rates in Portsmouth, Sheffield, Wolverhampton, and Birkenhead. The greatest mortality from measles occurred in Portsmouth, Plymouth, and Sunderland; from scarlet fever in Wolverhampton; from whooping-cough in Wolverhampton; from "fever" in Huddersfield; and from diarrhœa in Portsmouth, Leicester, Birkenhead, Salford and Sheffield. The 47 deaths from diphtheria included 21 in London, 5 in Liverpool, 4 in Leeds, and 3 in West Ham. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2321, against 2250, 2314, and 2355 on the three preceding Saturdays; 232 new cases were admitted during the week, against 237, 265, and 276 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 175 and 148 in the two preceding weeks, rose again to 173 last week, but were slightly below the corrected average. The causes of 41, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·5 and 20·1 per 1000 in the two preceding weeks, declined again to 18·6 during the week ending July 30th, but was 1·4 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 8·5 in Perth and 13·6 in Leith to 19·7 in Edinburgh and 24·0 in Dundee. The 560 deaths in these towns included 57 which were referred to diarrhœa, 25 to measles, 20 to whooping-cough, 6 to scarlet fever, 3 to "fever," 2 to diphtheria, and not one to small-pox. In all, 113 deaths resulted from these principal zymotic diseases, against 93 and 118 in the two preceding weeks. These 113 deaths were equal to an annual rate of 3·7 per 1000, which was 1·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The 57 fatal cases of diarrhœa showed a slight further increase upon those recorded in recent weeks and included 40 in Glasgow and 4 in Dundee. The deaths from measles, which had declined from 41 to 19 in the four preceding weeks, rose again to 25 last week, of which 13 occurred in Dundee, 5 in Glasgow, 3 in Edinburgh, and 3 in Leith. The 20 fatal cases of whooping-cough showed a decline of 9 from the number in the preceding week, and included 14 in Glasgow and 3 in Aberdeen. The deaths from scarlet fever, which had been 9 and 8 in the two preceding weeks, further declined to 6 last week, of which 3 occurred in Glasgow, where the 3 fatal cases of "fever" and the 2 deaths from diphtheria were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 76 and 75 in the two preceding weeks, rose again to 79 last week and exceeded by 13 the number in the corresponding period of last year. The causes of 29, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·5 and 22·7 per 1000 in the two preceding weeks, further rose to 23·9 during the week ending July 30th. During the past four weeks the death-rate in the city has averaged 21·4 per 1000, the rate during the same period being 15·2 in London and 19.6 in Edinburgh. The 160 deaths registered in Dublin during the week under notice showed an increase of 12 upon the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 3 and 12 in the two preceding weeks; of these, 9 resulted from diarrhœa, 3 from "fever," 1 from scarlet fever, 1 from diphtheria, and not one either from small-pox, measles, or whooping-cough. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 2·6 in London and 1·4 in Edinburgh. The deaths from diarrhœa, which had been 1 and 4 in the two preceding weeks, further rose to 9 last week. The 3 deaths referred to different forms of "fever" exceeded the number registered in any recent week. The mortality from scarlet fever and from diphtheria corresponded with that recorded in the preceding week. The 160 deaths in Dublin last week included 30 of infants under one year of age, and 39 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons showed a further increase upon the numbers recorded in recent weeks. Four inquest cases and 2 deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of 9, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NAVAL MEDICAL SERVICE.

FLEET-SURGEON THOMAS CANNING HICKEY, M.B. Glasg., has been placed on the retired list at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are announced:—Staff Surgeons: Edward C. Ward to the *Pengwin;* Hamilton Meikle to the *Severn;* and J. O'B. Williams to the *Vivid.*

ROYAL ARMY MEDICAL CORPS.

Major A. E. Tate takes over medical charge of officers,

Digitized by Google

women, and children at Colchester. Captain L. Way is placed on the sick list. Lieutenant-Colonel J. C. Dorman has arrived at Dublin.

Surgeon-General John W. Maxham retires on retired pay. Captain Phillip J. R. Nunnerley is placed on temporary half-pay on account of ill-health.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major Silcock to officiate as Civil Surgeon, Nagpur; Surgeon-Major Price as Civil Surgeon, Bilaspur. Surgeon-Captain Moir, Officiating First Resident Surgeon, Presidency General Hospital, Calcutta, is confirmed in that appointment. Surgeon-Captain O'Kinealy is appointed to be Second Resident Surgeon, Presidency General Hospital, Calcutta. Surgeon-Captain Deare, Civil Surgeon of Nadia, is appointed to act as Civil Surgeon, Midnapore, during the absence, on deputation, of Surgeon-Major Walsh. Surgeon-Major Crawford, Civil Surgeon, Monghyr, is appointed to act as Civil Surgeon of the 24 Parganas during the absence of Surgeon-Major Leahy and to act as Medical Inspector of Emigrants (Colonial Immigration) in addition to his own duties. Surgeon-Major Rogers is appointed to act as Civil Surgeon, Monghyr. Surgeon-Lieutenant-Colonel Comins, Inspector-General of Jails for Bengal, is allowed furlough for eighteen months. The services of Surgeon-Captain Manifold (Bengal) and Surgeon-Captain Young (Bengal) are replaced at the disposal of the Government of the North-West Provinces and Oudh.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain James Turton to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 1st North Riding of Yorkshire (Western Division, Royal Artillery): Patrick Bernard Gretton Considine, M.B. Dubl., to be Surgeon-Lieutenant. 4th West Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Lieutenant J. B. Milne, M.B. Aberd., resigns his commission. *Rifle:* 2nd Volunteer Battalion the East Surrey Regiment: Surgeon-Lieutenant T. Brushfield, M.B. Cantab., to be Surgeon-Captain. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Surgeon-Major G. Griffith to be Surgeon-Lieutenant-Colonel.

THE SPANISH-AMERICAN WAR.

The political situation and Spain's acceptance of the proffered terms of peace have for the time altogether usurped the place of war news. The Americans will nevertheless be confronted with great difficulties arising from the position which they will have to occupy in regard to the native and insurgent population and the future government and administration of the places to be evacuated by the Spanish troops. But it will necessarily take time to settle these matters, especially as regards Cuba, the Philippines and Manila. The force now advancing under General Miles at Porto Rico appears to be generally welcomed by the inhabitants and to be meeting with little or no opposition from the Spaniards. The Americans are to be sincerely congratulated on the capitulation and capture of Santiago, for General Shafter's expeditionary force, from sickness and other causes, was in serious straits. Fortunately, there has been no severe yellow fever epidemic at Santiago. The total casualties in action among the Americans up to July 15th were: killed—21 officers, 225 men; wounded—98 officers, 1486 men; missing—84 men; or a total of 1914 casualties. The sanitary report from the General shows that on July 28th last the number of sick had increased to 4279, including 3406 cases of fever. The new fever cases numbered 696, and the fever patients who had been restored to duty on the 28th, 590. Brigadier-General Steinberg, Chief of the Medical Department, fully appreciates the seriousness of the situation and is forwarding medical men and nurses to Santiago faster than ever. The sick and wounded prisoners in hospital number 2181. There are also many cases of typhoid fever among the troops stationed at different points in Florida, especially at Miami, where there are now 7500 volunteers under canvas, among whom "malarial typhoid" is very prevalent. Owing to the inadequate facilities for proper sanitation there Mr. Alger, Secretary of War, has ordered the camp to be transferred to Jacksonville. The sick transport service between Cuba and the United States does not seem to have been working satisfactorily. Some of the steamers carrying the sick and wounded have not been large enough or properly equipped and there has consequently been a good deal of overcrowding and great discomfort among the invalids. Much indignation, according to a correspondent writing in the *Daily Mail* on Aug. 2nd, was aroused in regard to the manner in which they were sent back to the States from Cuba in the steamer *Concho*, for example. This vessel left Santiago on July 23rd with 175 officers and men suffering from wounds and fever as well as a large number of other passengers. Five men died during the voyage, the sick on board became worse, and the healthy became ill owing to the bad sanitary arrangements and absence of any proper care and attention. The United States' Government has ordered a strict inquiry into all the circumstances of the alleged grave mismanagement. The complications in and around Manila are becoming serious, to say the least of it. The insurgent populations cannot be trusted to govern either in Cuba or in the Philippines, and the political situation may soon prove as embarrassing to the conquerors as to the conquered. American troops have already arrived, and are still arriving, to form a land force in aid of Admiral Dewey's fleet for the capture of Manila, about the speedy capitulation or fall of which city no doubt is entertained. The health reports of the men belonging to Admiral Dewey's fleet and of the soldiers composing General Merritt's force are fairly satisfactory. The President of the United States has shown himself to be a strong man and has greatly added to his reputation by his judicious and practical conduct of affairs during the war as well as by his moderation in dictating the terms of peace to Spain.

THE SOUDAN CAMPAIGN.

The health of the troops in the Soudan is good; there is now but little enteric fever and almost no dysentery amongst them. The men composing the force who have been occupying the Soudan have become well seasoned to the climate. They have throughout been well cared for in all respects—as regards food, water-supply, and housing—and their physical training has been maintained by route-marching and camp exercises of all kinds. The sick-rate has long been, and still is, under 6 per cent. Surgeon-General Taylor has reached the Sirdar's headquarters at Atbara camp. The railway is now completed to the headquarters' camp and has brought up large quantities of food and stores for the coming expedition to Khartoum. It is probable that no field army has ever been better supplied or looked after than the force about to advance against the Khalifa. It is expected that the capture of a fortified place like Omdurman, defended by a large force of fighting men, will be the toughest thing yet undertaken in our Soudanese warfare. We shall soon see. Meanwhile, Sir H. Kitchener has the merit of keeping his strategical intentions and military plans severely to himself. It will be an interesting and proud position to take part in an expedition which will avenge the death of Gordon—the most chivalric figure of this age—and liberate the native population from a grievous and cruel oppression.

"Audi alteram partem."

THE VACCINATION BILL.

To the Editors of THE LANCET.

SIRS,—The Bill as amended by the Standing Committee on Law provides (section 1, subsection 2) that "the public vaccinator of the district shall, if the parent or other person having the custody of a child so requires, visit the home of the child for the purpose of vaccinating the child." As an old inspector of public vaccination (under the Local Government Board) in Lancashire, Yorkshire (East and West Riding), Lincolnshire, Nottinghamshire, Derbyshire and Cheshire, I can have no doubt that if the above provision becomes law the attendance of parents with their children at a public vaccination station will soon absolutely cease and that consequently the Local Government Board inspector will be unable to certify by actual inspection whether or not the Board's instructions to public vaccinators are duly observed. The public will thereby lose the protection which the law now gives them. The use of a rusty or foul lancet (with all its possible risks) is not an imaginary evil.

I am, Sirs, yours faithfully,

CHAS. I. BEARD.

Keith-grove, Shepherd's Bush, W., July 28th, 1898.

To the Editors of THE LANCET.

SIRS,—That a subject which involves the health of the community should be made a mere party question in the

Digitized by Google

House of Commons clearly points to the necessity which exists for the official representation of the medical profession in that House. At present we are dependent on what may be termed accidental representation, a condition of things which, as we see, allows of tricks being played with public health.

I am, Sirs, yours faithfully,

Harley-street, W., July 27th, 1898. ARTHUR H. CHEATLE.

"THE ALLEGED DEARTH OF QUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—There is a statement in the letter in THE LANCET of July 30th signed "M.D. Edin." to which I should like to call attention and which is as follows: "That the acceptance of contemptible fees for responsible professional service is degrading to the individual and derogatory to the dignity of a learned profession is abundantly evident." I should like, therefore, to be allowed to ask your correspondent who takes such high ground, What, in the event of his doctrine being universally practised, is to become of the vast majority of the class who require medical aid but who at the same time are ineligible as recipients of Poor-law relief? Surely it must be evident to your correspondent that only a minority (and probably a very small minority too) of those resident within the British Isles are in a position to remunerate a medical man in any adequate sense of the term remuneration. It is true that clubs, provident dispensaries, hospitals, and the Poor-law exist, and these may be regarded by some as a more or less refined method of covering up or disguising low fees; but as concerns the smallness of the fee I venture to state they are equally if not more "contemptible" in point of pecuniary equation than those derived from a so-called "sixpenny dispensary," and I venture to state further that even if the Government were to undertake the remuneration of our profession, as hinted at by another correspondent, the fees would continue "contemptible," and we have a specimen of this under the present Poor-law system.

I am, Sirs, yours faithfully,

Peckham, S.E., Aug. 2nd, 1898. CLEMENT H. SERS.

THE INDEXES TO THE REPORT OF THE ROYAL COMMISSION ON VACCINATION.

To the Editors of THE LANCET.

SIRS,—Permit me, in thanking Dr. Bond for his complimentary notice of my Index to the Report of the Royal Commission on Vaccination and of that to the report of the dissentient minority, to point out an error into which he has inadvertently fallen. The indexes are not to be had here, as I have made over the copyright to the league, but from the secretary, Mrs. Young, 50, Parliament-street, S.W. As a second edition may be called for I should be much indebted for any errata that may be discovered and notified to me.

I am, Sirs, yours faithfully,

Edgbaston, Aug. 1st, 1898. A. PHELPS.

HOSPITAL REFORM AND SANITATION.

To the Editors of THE LANCET.

SIRS,—Having been requested to read a paper on Hospital Reform at the forthcoming congress in Dublin I shall feel grateful if some of your Irish correspondents will communicate with me on the subject. At first sight there does not appear to be much connexion between hospital reform and sanitation, but on reflection it will be acknowledged that there are several points which are well worthy of discussion at a sanitary congress. For instance, the reception of infectious diseases in a general hospital and the overcrowding of persons suffering from all sorts of diseases in the limited space generally allowed to out-patients are well worthy of the attention of sanitarians.

I am, Sirs, yours faithfully,

T. GARRETT HORDER,

Cardiff, Aug. 2nd, 1898. Hon. Sec. Hospital Reform Association.

PIPERIDINE: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In the general conclusions at the end of our paper on Piperidine as a Uric Acid Solvent contained in THE LANCET of July 23rd the dose of the tartrate is given as 15 gr. The dose in which we have employed the drug is 10 gr., as stated earlier in the paper.

We are, Sirs, yours faithfully,

F. W. TUNNICLIFFE.
OTTO ROSENHEIM.

Devonshire-street, Portland-place, W., July 27th, 1898.

THE CASE OF DR. REICHARDT.

To the Editors of THE LANCET.

SIRS,—It appears to me justifiable to ask for the support of the members of the medical profession when one of their fellows is attacked by a powerful body in regard to what he believes to be the proper conduct of his profession. I therefore write under the following circumstances.

Dr. Reichardt, of Ewell, who has had considerable experience in the treatment of nervous and insane patients, received into his house, at the suggestion of a leading consulting general physician, a young lady who was suffering from temporary mental depression, he having no other certifiable patient in his house at the time. After the lady had been with him a short time he called in a mental specialist to advise him as to whether the patient, who was still somewhat depressed, was in such a state as to require certification. The consultant decided that, in his opinion, she was not certifiable, and the patient began to improve in all ways till the reception of bad news seemed to upset her again, when she escaped from the house and drowned herself. Dr. Reichardt is now called upon to defend himself at the Old Bailey for alleged offences against the Lunacy Act, and it seems to me to be of the utmost importance to the profession generally that he should be placed in a position to justify the treatment in private of patients who are suffering from temporary mental disorders. I therefore beg to appeal to my medical brethren for pecuniary support.

I am, Sirs, yours faithfully,

GEO. H. SAVAGE.

3, Henrietta-street, Cavendish-square, W., Aug. 3rd, 1898.

THE EFFECT OF THE SOCIAL PURITY AGITATION AT GIBRALTAR.

(FROM A SPECIAL CORRESPONDENT.)

THE terrible prevalence of venereal disease at Gibraltar, accentuated by the interference of the Home Government, is a grievance which affects not only the colony itself but the Spanish towns of Linea, Algeciras, and other surrounding districts. If we read reports on the health of Gibraltar, whether written by the medical officers of health of the colony or by independent critics, a great number of complaints will be found concerning the difficulty of preventing the importation of disease from Spain. At one time it is typhoid fever, at another cholera or small-pox contracted in Spain and spread in Gibraltar; or else disease is imported by means of milk which is brought over from Spain and the distribution of which should be better controlled. Sometimes it may be due to the linen which is sent out from Gibraltar to be washed in Spain and is there dried or washed in dangerous proximity with cases of infectious disease. But if in Spain the sanitation and the drainage of the houses are bad and there are no efficacious means of disinfection, notification, and isolation for cases of infectious fever, very strict precautions are taken to prevent the spread of venereal disease. Undoubtedly some cases of zymotic disease are imported from Spain to Gibraltar, but these are few and far between as compared with the numerous cases of venereal disease spread in Spain from Gibraltar. It is surprising how patiently the Spaniards have endured this grievance, and it is a wonder that the Spanish authorities have not made strong protests against the dangerous neglect

Digitized by Google

of the British authorities. In justice to the inhabitants of Gibraltar it must be said that the enormous majority bitterly regret that the interference of the home authorities has brought this shame upon them. They never desired the abrogation of the Contagious Diseases Act, and when this law was rescinded they very ingeniously contrived to continue its application for many years. There was certainly no longer any power to compel women to undergo medical examination, but as the women in question were all Spanish subjects, or at least foreigners, they were not allowed to reside at Gibraltar unless they obtained a special permission to do so. This permission was refused to the women who could not produce weekly a medical certificate of good health. As these women were all accustomed to such medical examination in their own country this regulation constituted no hardship and was willingly accepted.

In 1890 the Social Purity party in England got wind of this arrangement and in that and the following year sent delegates out to Gibraltar. As usual they obtained the support of some members of the clergy and other unpractical sentimentalists. The result is that the police have been ordered to employ no force—in fact, that nothing is to be done. Formerly they did not compel the women to be examined, but they insisted that they should reside in certain houses and produce a certificate every week. The women therefore paid a local practitioner to examine them and thus procured the certificates. Of course, a woman who was a British subject could have refused to show a certificate and the police would have been powerless; but fortunately all, or nearly all, of these women were foreigners and could therefore be sent away if they failed to comply. Indeed, the only measure which can now be taken is to send the women away. The practical result of this state of things is certainly not edifying. A great number of these women have paid Gibraltar British subjects to marry them. They have thus acquired the British nationality. They can therefore defy the police, no one can deny their right to reside in Gibraltar, and one of the first results of the Social Purity agitation has been to induce a number of men to marry prostitutes and to live on the prostitution of their wives. Then, again, as the legitimate wives of British subjects these women can live in any part of the town, whereas formerly they were relegated to certain districts high up on the ramparts where their presence remained unperceived by the more virtuous section of the population.

The Social Purity party have said a great deal about the dignity of women and have represented them as being enslaved and degraded by enforced medical examinations. It would seem, however, as if the women concerned do not appreciate very keenly these arguments. They recognise, on the contrary, that the abolition of the Contagious Diseases Act has proved detrimental to their interests. Disease became so prevalent that the women not only suffered physically but also financially. The men began to shun them and went over to the Linea and other Spanish places. So it has come to pass that the women at Gibraltar for whose sake the law and regulations enforcing medical examinations have been abolished are now seeking by voluntary means to re-establish the very practice which was denounced as so abominable. I was assured by the police authorities that at least half of the public women at Gibraltar at their own expense and every week obtain a medical certificate. Soldiers and sailors and the civil population also are better educated than they used to be and are consequently much more careful. They therefore prefer women who can produce medical certificates and often ask for these certificates. If these certificates, as is urged, encourage vice—a very doubtful and problematical statement—then the abolition of the law has not secured the abolition of the certificates. On the other hand, it must be acknowledged that the usefulness of these certificates is not as yet very great. For instance, when, as is often the case, a woman's name is not known, she can borrow and show the certificate of some other woman. Again, if on examination it is found that she is ill there is no force to compel her to undergo treatment. She can no longer produce other than a borrowed certificate, but there is nothing to prevent her spreading the disease she has contracted. Thus, in spite of the voluntary certificate system, there is still much disease prevalent. Nevertheless, and though the results so far are not very effective, it is most significant to find that the women themselves voluntarily seek to re-establish those regulations which they were supposed bitterly to resent.

According to the police, there are now in Gibraltar about a hundred of what are qualified as "professional" prostitutes and about sixty "clandestine" prostitutes. The civil population of Gibraltar for the year 1897 was estimated at 19,100. The garrison is under 5000. The average strength of the troops amounted to 4630 in 1896. But if the number of women is not larger it is because most of the men go over to the Linea, where they find a cleaner and better class of women. Under these circumstances the Spaniards would be quite justified in urging that the same precautions should be taken at Gibraltar as are taken at the Linea; and, in any case, while this state of things continues it is most inconsistent for us to complain that the same precautions are not taken on the Spanish side to prevent the spread of infectious fevers, &c., as are actually enforced in Gibraltar. The consequences of syphilis are quite as serious as those of scarlet fever or small-pox. We render notification, isolation, disinfection, and vaccination obligatory, thus totally disregarding the liberty of subjects against whose respectability nothing can be said. Yet we will not interfere with the liberty of women who are certainly not qualified as respectable and who are notoriously likely to spread a very terrible disease. This gross inconsistency should silence the complaints which the inhabitants of Gibraltar are in the habit of making as to the insanitary conditions which prevail on the Spanish side and which add to the difficulties of preserving the health of Gibraltar. It is notorious that there is a great increase of venereal disease at Algeciras during the summer months. Nor is it necessary to go far to find an explanation of this phenomenon. The climate of Algeciras is much pleasanter than that of Gibraltar during the heat of summer. Then there is a brilliant fête at Algeciras and bull-fighting. Consequently a great number of people go over from Gibraltar for the summer season, as it is barely half-an-hour's journey by the steamer which crosses the bay. It is these visitors from Gibraltar who spread venereal disease at Algeciras. The medical men who examine the women at Algeciras are unanimous in bearing witness to this fact. Further, they declare that nearly all the women who come from the Linea are found to be diseased; in fact, the women from the Linea have acquired a bad name and are studiously avoided by the Spaniards because of their constant relations with the English. The medical men at Algeciras explained to me that they were very careful to at once examine any woman who came from the Linea and they generally found such women diseased. The Linea was too near to Gibraltar to be anything else but an exceptionally dangerous residence for them.

The difficulty of obtaining permission to reside in Gibraltar has also a tendency to encourage immorality. If a Spaniard lives with a Gibraltar woman and has children the woman and her children can remain because they are British subjects. But if the Spaniard marries the woman then she and her children, legally speaking, become Spaniards and unless they succeed in obtaining a special licence to remain they are all sent away. If the man dies the widow is only allowed to reside three months in the colony; or, perhaps, this licence may be extended to six months. Under these circumstances, as there is money to be made in Gibraltar and in all probability none to be made in Spain, a Gibraltar woman who falls in love with a Spaniard had better, so far as her material interests are concerned, avoid contracting a legal marriage.

Of course there are no statistics showing to what extent venereal disease prevails at Gibraltar as well as these which relate to the garrison. The last published relate to the year 1896 and state that the average strength of the troops was 4630. The average number constantly sick was 246·74. The number of admissions to hospital was equal to 699·5 per 1000, the deaths to 4·10 per 1000, and the constantly sick to 53·29 per 1000. This is a reduction on the figures of the previous year. Taking out of this general total that which relates to venereal diseases it will be found that there were 27 admissions to hospital for primary syphilis, which is equal to 5·8 per 1000, a considerable reduction on the experience of the previous year, when the proportion was 8 per 1000. Then there were 302 admissions for simple venereal ulcer, and this is equal to 71·1 per 1000. For secondary syphilis there were 97 admissions, or 21·0 per 1000, as compared with 27·2 per 1000, the average for the last decennial period. For gonorrhœa there were 655 admissions, or 141·5 per 1000, which is a trifle less than the previous year, but more by 18·6 per 1000 than the last decennial average. Taking all forms of venereal disease together the proportion stands

Digitized by Google

at 233·6 cases per 1000, as compared to 316·2 per 1000 for 1895 and 269·2 for the decennial average. The ratio of constant inefficiency was equal to 25·69 per 1000, which is lower by 5·96 than the previous year but 4·12 per 1000 higher than the average. Thus the inefficiency of the force in consequence of illness in 1896 was equal to 52·29 per 1000, and more than half of this loss—namely, 25·69 per 1000—was due to venereal disease. What this means with regard to the fighting capacities of the force is self-evident. It is not necessary to enlarge on this phase of the subject. It is only necessary to compare the above figures with similar statistics relating to any continental army to understand the manifest inferiority in this respect of the British as compared with any other army. If by thus weakening our forces any great moral good could be achieved then it might be worth while to endure this sacrifice. But experience acquired at Gibraltar shows that by abolishing the medical examination of women worse phases of immorality have resulted. We have encouraged men to marry prostitutes and to trade on their prostitution. The "social evil" has not been abolished, it has been accentuated.

THE SPANISH-AMERICAN WAR.

(FROM SPECIAL CORRESPONDENTS.)

On board Hospital Ship *Relief*, near Santiago, July 7th, 1898.

OUR voyage here was without incident and was broken only by a short stop at Fortress Monroe, where we met the Surgeon-General of the Army and took on board a number of surgeons for whom General Shafter had telegraphed on finding the casualties far in excess of what he had at first supposed. Among those who joined the *Relief* was Dr. Nicholas Senn, of Chicago, who goes to Cuba as chief of the operating staff with the army in the field. He will give naturally special attention to the perfecting of the newly-established system of division hospitals.

Dr. Senn expressed himself as delighted with the general arrangements of the ship, though he has made some suggestions for its improvement in certain details. The cots, for instance, are fitted with wooden fenders to prevent patients from being thrown out; these, Dr. Senn said, should without doubt have been of canvas.

The hurricane deck is to be used for typhoid or other infectious fever which may develop on board. Dr. Senn called attention to the fact that in all properly appointed hospitals the fever wards were on the lower floors, and not on the upper floor as in this ship. He is of the opinion, however, that under no circumstances should cases of infectious disease be allowed to remain on board ship; they should at once be removed to a shore hospital. We were shocked on arriving at Fortress Monroe to hear that there had been over a thousand killed and wounded in the first fight at Santiago. The painful fact was forced upon us that if the casualties continued in this proportion we should be woefully in need of more hospital space, which only goes to emphasise the necessity not of one, but of many such ships as this. The truth is that neither the powers that be nor the people appreciated for a moment what they had undertaken in this war. Then, too, the extraordinary freedom from casualties which characterised the operations of our fleets in the Atlantic and the Pacific led to the belief that the Spanish could not shoot and would not fight; in short, that we should have an easy time of it.

Santiago itself is a hotbed of yellow fever, and a high authority, whom I cannot quote by name, said that if we invest the town we are sure to have an outbreak of this dread disease, with a loss of 25 per cent. I asked Dr. Senn if the climatic conditions around Santiago were likely to lead to bad results after amputations and other operations. He replied that, other things being equal, heat and humidity did not militate against rapid healing; so that it will doubtless be a source of gratification to those who have loved ones in the field to know that the after-results of operations in this climate are, as a rule, so satisfactory.

We arrived at Siboney this afternoon to find that about 2000 men had been killed and wounded. The medical corps suffered severely. The Spaniards did not respect the Red Cross, having fired repeatedly upon the ambulances and at wounded men on stretchers. This is a severe charge, which I make unreservedly upon the authority of a dozen men, surgeons and officers who were at the front. Colonel Dickinson was shot twice, once while being carried to the tent, and a second time, and this time fatally, just as he was entering the tent. Two surgeons and a hospital steward were killed in the same way. When Dr. Torney and Lieutenant Gobbs went ashore they wore the Red Cross brassard. The first remark which the wounded men and the surgeons made to them was to advise its removal, for far from being a protection it but served as a mark for the Spanish. This conduct on the part of the Spanish was in the face of the fact that they had Red Cross flags flying all over Santiago.

The condition of the wounded on shore here is beyond measure wretched and excites the lively indignation of everyone. I content myself with mentioning this fact—it is not the fault of the medical corps. The quartermaster and commissary departments are to blame. We were distressed not to be able to take the sick and wounded on board this afternoon, but owing to some official red tape Dr. Torney was not given an anchorage—the shore, of course, had been prepared for the ship. Why this was not done when the wounded so sorely needed the comforts and attention which we can give them is a mystery officialdom will have to explain.

We begin to take on the wounded to-morrow morning at 4 A.M. I close this to catch the transport about to sail. There is no sickness on board the *Relief*.

Another correspondent writes:—

In Camp on the Hills, near Santiago, Cuba, July 6th, 1898.

I am glad to be able to write to you after the hot engagement we had recently with the Spanish. As regards the wounds inflicted, the Spanish are using two kinds of rifles, the one loaded with the Mauser steel-jacketed bullet similar to our bullet, but of slightly smaller calibre and more pointed, calibre 27.+; and the other with the Remington brass-jacketed bullet, calibre 44. The firing has been mainly at medium range, about 700 or 800 yards. The main thing noticeable was the slight amount of shock following injury by the Mauser bullet and the great amount of shock with the Remington. As my work was altogether that of first aid, I know nothing of the damage done internally, but in the cases handled by me which were many, the Mauser balls appeared to make nothing more than a clean punctured wound, that of exit being hardly if any greater than that of entrance. The amount of bleeding was practically *nil*, even in perforating wounds of the lung. The percentage of killed was small as compared with the number of wounded and in consequence of the small degree of shock the majority of the latter are doing well and some are already back on the firing line. There was very little shattering of bone; personally, I did not see a single case. Some men with brain-perforations lived forty-eight hours after reaching the division hospital. The penetrating abdominal wounds were necessarily serious and the shock severe. It will be interesting to follow their history when report can be had of their subsequent behaviour after reaching the hospital. A number of the wounded were hit several times before becoming disabled sufficiently to prevent fighting. The results from the larger bullets were more like those from our bullets during the late war: large wounds of exit, great shock, and probably considerable damage along the track of the ball. I saw several of these bullets with torn, jagged jackets, which made severe injuries. It is said that protest has been made against the use of the brass-jacketed bullet, both by our people and the foreign attachés here with us, as a violation of the article on projectiles in the Geneva Convention, for the reason that the brass jacket is an irritant to the tissues and the soft lead core in it is liable to make it spread and inflict injuries like those made by express bullets. It is believed that this bullet is used by the guerillas among the Spanish.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The "Weighting" of Textiles.

AT the meeting of the Manchester Chamber of Commerce held on the 27th ult. a matter came under discussion illustrative of the views which some manufacturers hold as to commercial morality and interesting to the medical profession from its bearing on health. Mr. W. Fogg called attention to a note in the *Manchester Guardian* of that morning in regard to the "weighting" of woollen blankets with moisture-attracting

Digitized by Google

substances such as those employed in low-priced sheets made from cotton waste. He said that they were indebted to Mr. Carse for bringing this pernicious practice, which is believed to be growing, under the public eye. A manufacturer wrote to him as follows: "We have the same evil to contend with in the blanket trade that you have hit on the head in the waste twill sheet trade, and blankets will soon be as dangerous to sleep under as sheets if certain practices in filling are allowed to go unchecked." He says if they do not follow suit they will lose all their trade. We may hope the judgment and good sense of the people will come to the rescue. "Another manufacturer had been candid enough to say that he would not sleep under a pair of his own sheets for £100." Mr. Reuben Spencer said that "the mixtures of zinc and Epsom salts used for weighting purposes were very deleterious in the effects they produced, though it was to be said for them that they were fatal to insect life." The boasted integrity of the British merchant and manufacturer promises before long to become a legend incapable of belief. A resolution was passed unanimously: "That the president be requested to call the attention of the Home Trade Sectional Committee to the practice of 'weighting' textile fabrics used for clothing with moisture-attracting materials, with a view to devising the best method of dealing with the evil." It is discreditable to British trade that such a resolution—which will by no means disturb the minds of those who are wicked enough to endanger the health of all who use their goods—should have to be put on record.

Cotton Districts Convalescent Fund.

The almost forgotten cotton famine is again brought to mind by the meeting of the governors of the Cotton Districts Convalescent Fund, which was held the other day under the chairmanship of Lord Egerton of Tatton, who was supported by many noblemen and gentlemen of Cheshire and Lancashire. The report stated that during the half-year ending June 30th 1278 patients had been sent to the convalescent hospitals at Southport, Buxton, and Cheadle, at a cost of £2085 5*s.* 1*d.*, as against £2395 15*s.* 4*d.* in the corresponding period last year, when 1379 patients were admitted to the institutions through this fund. It stated also that the Convalescent Hospital and the Children's Sanatorium at Southport had been recently visited by several members of the Hospitals Committee, who found the patients comfortably quartered and attended to, while the day-rooms, dormitories, and administrative offices were clean and orderly.

The Stockport Union Workhouse.

The question of workhouse accommodation has exercised the minds of the Stockport Union Guardians for some time and the enlargement of the present workhouse or the building of a new one has been the subject of very animated discussions. That something should be done quickly is evident from the report of Mr. W. B. Bale, the medical officer, which was read at the meeting of the guardians held on July 28th. He stated that the female imbecile wards were so overcrowded that six of the inmates had to sleep in the body of the house, which was a cause of anxiety and danger. The floor of one ward is said to be so rotten as to be dangerous, but the difficulty is to find a place for the 40 women inmates during the necessary repairs. In the meantime, according to the newspaper reports, the guardians spend their time in wrangling over—or discussing in an animated fashion—the building of a new workhouse at Stepping Hill or acquiring property at Shaw Heath to permit of the extension of the present workhouse.

Aug. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of the Very Rev. Principal Caird, D.D.

IT will be with very genuine regret that graduates of the University of Glasgow will read of the death of Principal Caird. But a few weeks ago the intimation of his resignation was accompanied by what were believed to be well-founded hopes that the most serious features of his illness had subsided and that there remained for him a period of quiet in the evening of his life. Unfortunately, these hopes have proved groundless and during the closing days of last week his strength rapidly declined and he died early on the morning of July 30th. Dr. Caird had been Principal of the University for more than twenty-five years. As a pulpit orator he stood in the very front rank and his annual address to the students—discontinued in recent years in consequence of failing health—used to be one of the features of the session. It is almost impossible to over-estimate the influence which he exerted on the life of the University, and many hundreds of former students will recall his dignified presence, lofty eloquence and sympathetic insight with pathetic and affectionate regret.

Queen Margaret College, Glasgow.

The University Court have appointed Mr. William MacLannan, M.B., C.M. Glasg., to be lecturer on Materia Medica and Therapeutics in Queen Margaret College.

Appointments under the Workmen's Compensation Act, 1897.

The following gentlemen have been appointed medical referees under the above Act:—Inverary: Mr. James Stewart; Oban: Dr. Dove M'Calman; Dunoon: Dr. John Ritchie; Campbeltown: Dr. John Cunningham; County of Berwick: Dr. John M'Watt; County of Linlithgow: Dr. J. C. Dunlop; Sheriffdom of Perth: Dr. Alex. Thom.

Memorial to the late Dr. Greig Smith.

A neat tablet in artistic brass has been placed on the wall of the lobby of the Aberdeen Students' Union. The inscription runs: "In Memory of James Greig Smith, M.A., M.B., C.M. Aberdeen, Professor of Surgery, University College, Bristol. This tablet is erected by his friends to commemorate his attainments as a surgeon and to recall his career to the students of the University of Aberdeen. Born 1854; died 1897."

Aberdeen University Buildings Extension.

The University authorities have every reason to expect at a very early date an additional donation of £15,000 to the funds for this scheme. A conference of various bodies is to be held soon as to the proposed retention of old Greyfriars Church which was made a condition of a gift of £10,000 offered by an anonymous donor.

History Lectureship, Aberdeen University.

Mr. Charles Sanford Terry, Clare College, Cambridge, has been appointed Lecturer in History by Aberdeen University Court. There were ten candidates. Mr. Terry is at present Lecturer in History in Durham College of Science, Newcastle.

Aberdeen Medical Volunteer Staff Corps.

Forty men of this corps left Aberdeen on July 29th for Aldershot for a week's training and for the purpose of taking part in the military manœuvres on Aug. 5th, along with detachments from the Universities of Edinburgh, Glasgow, and London. On finishing their training the men have the option of going home or of staying in the metropolis till October with the object of attending the large hospitals there.

Aug. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Queen's College, Belfast.

AT the medical class examinations held at the close of the summer session in the above College the following prizes were awarded:—Botany.—Sydney Herbert George Blakely, Robert James Bethune, Henry Mulrea Johnston, John M'Clatchey, James Hamilton Campbell, and James Kennedy Small. Practical Chemistry.—Senior: William Rodgers, M.A. Junior: John Knox, Samuel Hugh Whyte, and Alexander M'Cloy. Systematic Pathology.—William Matthew Hunter, Robert Steen, and Annie Helen Crawford. Practical Pharmacy.—John Hope Retford, B.A., and Marion Braidfoot Andrews.

Death of Mr. A. C. McCutcheon, L.R.C.P. & S. Irel.

I regret to announce the death at Wakefield, Yorkshire, on July 23rd, of Mr. Andrew C. McCutcheon. About three weeks ago he was seized with acute inflammation of the stomach and on July 23rd a serious change set in and he sank that night. A native of Ballymena, where his father is well known, Mr. McCutcheon studied in Dublin and gained many prizes at the Meath Hospital and at the Dublin College of Surgeons whose diplomas he obtained in 1892. Eighteen months ago he settled down in practice in Wakefield, Yorks.

Digitized by Google

where he was most popular with his patients. He was buried in Ballymena on July 26th, an immense concourse of friends following his remains to their last resting place. The greatest sympathy is expressed for his relatives in their sad bereavement.

Death of the Queen's Oldest Subject.

Mr. Robert Taylor, postmaster of Scarva, county Down, the oldest subject of Her Majesty the Queen, died at his residence Scarva, county Down, on July 25th. His age was problematical, but it is alleged that he was born in 1764, the date being arrived at by comparison of events current in his youth and with which he was more or less connected. It is based on statements made by himself many years ago, and those who in former times were intimately acquainted with him hold that he was 134 years of age. Others fix his birth year as 1780, which would make his age 118 years. Although latterly his physical strength was gradually decreasing his mind was clear until the end. A few months ago the Queen sent Mr. Taylor a beautifully-framed portrait of herself with the following inscription: "This picture is presented by Queen Victoria to Mr. Robert Taylor, postmaster of Scarva, on his having attained an almost unprecedented age, April, 1898." By his death the Queen has lost her oldest subject and county Down its grand old man. Those who are interested in centenarians may like the following, taken from the *Northern Whig*, a Belfast newspaper, for reference:—

County Down appears to be exceptionally favourable to longevity. Scores of centenarians have lived and passed within its borders during the last 300 years. We read of Adam Montgomery, who "lived so long in sound health (105 years) over in the Ards that he would play at hide-and-seek with his great-grandchildren." More remarkable was Alexander Bennett, who died in his 125th year at Downpatrick in 1745. Within a period of seven years (1749-56) died four such persons in Rathfriland—Jane M'Afee, 115; Isabel Laughlin, 118; Alexander Mackenzie, 120; Jane Mackenzie, 114. Doubtless the latter two were husband and wife. Two other Rathfriland men survived—to 106 Henry Cowe, 121 Samuel Malcolmson. The oldest of whom we have record was James Thomson, 131, who expired at Ballynahinch in 1796. James Martin, 112, and Mary M'Dowell, 118, also belonged to Ballynahinch, and others are associated with almost every town in the shire, the latest in the present century being Joseph Carnaghan, Warlingstown, 108, and Peter White, Loughbrickland, 106. All of these were notable examples of perseverance and the effects of a salubrious climate, but none of them bore the burden of life so well or so lightly as Robert Taylor has done.

Queen's College, Belfast, and the Royal University of Ireland.

At the recent examinations of the Royal University of Ireland, Queen's College, Belfast, obtained 18 first honours, 28 second, and 18 exhibitions, or a total of 64 high distinctions. For comparison's sake the corresponding figures for other colleges may be given. They are as follows: Queen's College, Cork: no honours and no exhibitions. Queen's College, Galway: 4 firsts, 7 seconds, and 5 exhibitions; 16 in all. Magee College, Derry: 2 firsts, 4 seconds, and 1 exhibition; 7 in all.

The Ulster Eye, Ear, and Throat Hospital.

At the twenty-seventh annual meeting of this hospital, held on July 26th, it was reported that the total number of patients for the past year was 1507, and of these 220 were admitted into the hospital. The total receipts for the year were £655 0*s.* 5*d.* and the disbursements amounted to £941 11*s.* £381 16*s.* 10*d.* were received from intern cases and £120 3*s.* 10*d.* at the extern department. The total debt of the hospital now on general account is £470 12*s.* 1*d.* The whole hospital buildings and furniture have been insured for £6400.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The International Congress on Tuberculosis.

THE fourth international congress on Tuberculosis opened in Paris on Wednesday, July 27th, at the Faculty of Medicine. The large theatre was entirely filled by a crowd of medical men, among whom were a large number of foreigners. The presidential chair was occupied by M. Nocard, Professor at the Veterinary School at Alfort, supported by M. L. H. Petit (general secretary) and Professor Brouardel, Professor Bouchard, Professor Potain, Professor Lannelongue, Professor Grancher, Professor Cornil, and others. M. Nocard delivered an opening discourse in which he eulogised Villemin and Verneuil, who were the original organisers of these congresses. He reiterated the assertion that contagion played a large part in the etiology of tuberculosis, giving it as his firm opinion that the complaint was one of those which were most easy to avoid and that out of 150,000 persons who yearly fell victims to tuberculosis in France 125,000 might have been saved if they had been protected from contagion. Next M. Petit, the secretary, gave an account of what had resulted from the application of the measures suggested by the congress of last year. The two first, which dealt with the question of providing spittoons in public elementary schools so as to train the children not to spit on the floor, have only just begun to be applied. The third measure, which declared that tuberculosis ought to be numbered among the infectious diseases and that its notification ought to be obligatory, has not been acted upon. The fourth measure, which related to the compulsory disinfection of places where tuberculous patients had died, is at present being carried out fairly completely, at least in Paris and the large towns. The last measure, which dealt with the question of receiving tuberculous patients in special hospitals, or of isolating them in general hospitals, has been acted upon in so far that at the Lariboisière Hospital, at the Laennec Hospital, and at the Boucicaut Hospital, wards have been set aside for the isolation of such patients. Six millions of francs (£240,000) have been reserved for the building of such wards in the hospitals of St. Antoine, Cochin, Broussais, Bichat, La Pitié, Tenon, and in a new hospital to be built on the right bank of the Seine. — The congress then commenced the hearing of papers and reports. Professor Bang, of the Veterinary School of Copenhagen, read a most important paper on the struggle which was going on against animal tuberculosis by means of prophylactic measures. He referred briefly to various measures taken in Europe for the inspection of meat exposed for sale which had been taken from tuberculous animals as well as the transmission of tuberculosis by milk. The most interesting statement he made was in reference to the regulations introduced this very year in Denmark, which absolutely forbid any dairy to sell separated (*écrémé*) milk without its being previously heated to a temperature of 85° C.; after this it is quickly cooled, which prevents it having any peculiar taste. Professor Storch has discovered a test to show that the heating to 85° C. has been really carried out, for milk treated in this way preserves its colour when there are added to it a drop of a solution of peroxide of hydrogen and 2 drops of a 2 per cent. watery solution of paraphenylendiamine, whilst milk which has not been heated to 85° C. turns blue.—Various papers followed, notably one by M. Letulle upon the Present Provision for Tuberculous People in Hospitals in Paris; one by MM. Arloing and Courmont upon the Employment and the Clinical Value of the Agglutination Test; and one by M. A. J. Martin on the Increase in Applications for Disinfection after the Death of a Tuberculous Patient, which were sent in by the public and which numbered 7000 for the first half of 1898.—The second matter for discussion on the programme was the application of the x rays to the diagnosis and treatment of tuberculosis. M. Claude read a very important paper on the subject of Diagnosis, and referred to the progress which had been made in the matter by means of the rays. M. Espina of Madrid related how he had made a very early diagnosis by this method. M. Bedard described how he had diagnosed a tuberculous hip-joint at its very commencement in the same way. Various members reported researches which they had made as to the action of the x rays on the vitality of Koch's bacillus both in living tissues and in cultures.—The third matter for discussion was the treatment of tuberculosis by serums and toxins. M. Landouzy gave a very complete account of the whole matter in a long paper. M. Maragliano detailed his method of treatment by toxins. Professor Hirschfelder of San Francisco has treated tuberculosis by the oxytuberculine obtained by heating tuberculine for 120 hours with oxygenated water. M. Arloing and M. Guinard have been studying the physiological effects of the different products obtained from cultures of Koch's bacillus.—Besides the actual meetings of the congress at the Faculty of Medicine various demonstrations have been given during its sittings. On the morning of July 27th members paid a visit to the Boucicaut Hospital, where M. Letulle showed the special appliances which they possessed for the treatment of tuberculosis. On the evening of July 28th an x ray demonstration as regards the diagnosis of affections of the chest was given in the physical laboratory at the Faculty of Medicine by Professor Gariel, and a similar demonstration was given on July 30th at the Charité Hospital by Professor Bouchard. On July 29th at the St. Louis Hospital in the dermatological clinic of Dr. Hallopeau, Professor

Digitized by Google

Bang of Copenhagen gave a demonstration of Professor Finsen's method of treating cutaneous tuberculosis by coloured and concentrated luminous rays. Sunday, July 31st, was devoted to a visit to the environs of Paris, in the course of which the various special hospitals established for the treatment of tuberculosis at Ormesson and at Villiers-sur-Marne were inspected.

Medical Clubs.

A scheme for the organisation of a medical club in Paris has just been put forward by Dr. Doléris. Its object is to form a rallying centre for foreign and provincial medical men during the exhibition of 1900, and the idea has already been fairly well received. It is also announced that a medico-pharmaceutical club has just been founded at Lille, and that it now numbers eighty members.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Navy Full Diet Table.

THE medical officers of the United States Navy have adopted a new full diet table for one day as follows (the number after each article relating to the ounces):—Breakfast: coffee, 1; bread, 4; butter, 1; milk, 6; sugar, 1; oatmeal, 1; beefsteak, 6. Dinner: rice-soup, 8; bread, 4; roast beef or roast or boiled fowl, 8; other vegetables, 6; pickles, 1; bread pudding with sauce, 6; or custard, 8; fresh fruit, 6. Supper: tea, 1-4; bread, 6; butter, 1; milk, 2; sugar, 1; cold roast mutton or cold roast beef, 4; stewed dried fruit or baked fresh fruit or apple sauce, 4. The staples, as coffee, bread, butter, milk, sugar, and fresh and dried fruits are the same for each meal, but there is a daily variety in meat and other articles for breakfast, dinner, and supper.

Liquid Air in Medicine and Surgery.

It was an Englishman who discovered how to produce liquid air, but an American has carried the investigation a bit further and now tells us how this discovery can be put to practical use, stating that in medicine and surgery its possibilities are vast. It is claimed that by means of this process air absolutely free from germs could be furnished in any amount, and if the stimulating effect of an excess of oxygen were desired it could be had without trouble quite free from the impurities which now make this gas so often objectionable. The temperature of hospital wards even in the tropics could readily be cooled to any degree prescribed by the physicians in charge, and by keeping the air about yellow-fever patients down to the freezing point the nurses would be perfectly protected against contagion and the recovery of the patients themselves facilitated. Again, the cauterising cold which liquid air is capable of producing might be used in cases of cancer with great benefit as compared with nitrate of silver since while it absolutely destroys the flesh to which it is applied its action is perfectly under control and can be stopped in an instant. It is probable, also, that hay fever, asthma, and even consumption could be greatly relieved without change of climate by this pure, cool, germless air.

The Michigan State Board of Health.

This board is about to celebrate the quarter centennial anniversary, and an effort will be made to place before the citizens of Michigan accurate comparative statements of the conditions affecting the public health, and of the actual conditions of health in Michigan before and since the board of health was formed, especially exhibiting, if it be true, that there has been a very marked improvement of the health of Michigan in recent years; statements of the principal dangers to life and health at the present time; a discussion of different measures for the further promotion of the public health of that State, and to place before those who may visit Michigan on that occasion the beauties of the various summer resorts around the Great Lakes and at the numerous inland lakes and other sanitaria, the general healthfulness of the State, and its advantages as a summer resort State.

The Maritime Provinces of Canada as a Summer Health Resort.

The popularity of the maritime provinces of Canada as a holiday resort has been rapidly increasing during the last few years. In the warmer months tourists have been going there in larger and larger numbers, crowding the steamers and trains and overflowing the hotels. The increase in the number of tourists has really been so great of late that it was difficult to provide sufficient accommodation in many of the favourite localities, and in numerous places visitors have had to put up with inconveniences which almost amounted to hardship. Now that the people have become aware of the popularity of the provinces, the business instinct has awakened and every effort has been put forth by railway, steamboat, and hotel men to prevent a repetition of the uncomfortable overcrowding to which the tourists of the last two or three seasons have had to submit. The train and steamboat service is to be augmented, so as to provide for any contingency, and numerous hotels have already been, or shortly will be, completed in the localities where the congestion has been most marked in times past. All this is being done because of the assurance that future seasons will bring even greater numbers of visitors than in the past.

American Sanitation of Havana.

The Louisiana State Sanitary Association recommends that as nearly every epidemic of yellow fever which has ruined our commerce and ravaged our shores has had its origin in the colony of convalescents, Havana, our representatives in Congress be requested to lay before the proper Federal authorities the necessity of stamping out the yellow fever there, to the end that when the war now existing between Spain and the United States is ended and the articles of peace are drawn up it shall be nominated in that bond that "the sanitary regulations of Havana shall immediately commence under the surveillance of American sanitarians and engineers." The same association approves the plan of having medical inspectors attached to those consulates where yellow fever and cholera are epidemic with a view to securing for our protection definite information as to the exact sanitary condition and the presence or absence of contagious diseases in such consular districts and that congress be urged to make the necessary appropriation to carry the plan into effect. Also this association is of the opinion that it is a duty devolving upon all nations to take measures to eradicate any plague centre from their territory, and that the existence of such centres is a menace to all nations, and that our State department be requested to take measures through proper diplomatic channels for the conveyance of this opinion to the governments deemed obnoxious to the opinion herein expressed.

July 19th.

Obituary.

WILLIAM FRANCIS ADAMS, L.R.C.P. LOND., M.R.C.S. ENG.

MR. W. F. ADAMS, the senior assistant medical officer at the Cornwall County Asylum, Bodmin, was found dead in his bed on July 27th. He was the youngest son of Mr. Richard Adams, L.R.C.P. Edin., M.R.C.S. Eng., who a few months ago resigned the post of medical superintendent at the Cornwall County Asylum after having held the appointment for many years. The deceased, who was only twenty-six years of age at the time of his death, received his medical education at the London Hospital and obtained the qualifications of L.R.C.P. Lond. and M.R.C.S. Eng. in 1892. Shortly afterwards he was appointed junior house surgeon at the South Devon and East Cornwall Hospital, Plymouth. Mr. Adams had a lifelong connexion with the Cornwall County Asylum and his recent appointment on the medical staff was a very popular one. Much regret is felt at his early death and the deepest sympathy is expressed in Bodmin for his bereaved parents. At the inquest held on July 28th a verdict was returned of "Syncope resulting from fatty degeneration of the heart."

POOR-LAW CONFERENCE.—Lord Edmond Fitzmaurice, M.P., presided at the South-Western Poor-law Conference held at Plymouth last week. Dr. H. Rayner contributed an interesting paper upon the Treatment of Pauper Imbecile and Feeble-minded Children. A resolution was passed stating that it was imperative to make special provision for the treatment of these children and advocating the establishment of one or more central institutions in the south-western counties for the purpose,

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT EDINBURGH.

THE sixty-sixth annual meeting of the British Medical Association came to a successful termination on Saturday last.

Principal Sir William Muir, the President, and the other members of the Senatus Academicus of the University of Edinburgh held a reception on Thursday, July 28th, to which members of the British Medical Association were bidden. The guests were received in the library hall of the University and there was a large attendance. Sir William Priestley, the representative of the University in Parliament, has recently borne the expense of the redecoration of the library hall and his generosity has been well expended. The fluted pillars have been painted cream colour with white stone bases; the panels in the roof have been tinted light blue, and the carved mouldings and frieze have been gilded, the background being a deep red. The electric light was used for the first time in the building on this occasion.

A reception was also given on Thursday afternoon to the Association by the President and Fellows of the Royal College of Surgeons of Edinburgh in the Surgeons' Hall. There was a large gathering of guests, more than 300 ladies and gentlemen being present. The guests were received in the committee-room by the President of the College, Professor Chiene, with whom were Mrs. Chiene and several of the office-bearers of the College. There was a reception by the Royal Medical Society in their rooms at Melbourne-place on the same afternoon. The Presidents of the society, Dr. T. A. Ross, Dr. H. S. Ballantyne, Professor G. L. Chiene, and Dr. E. E. Porritt, received the guests, who numbered between 200 and 300, in the large hall, which was tastefully decorated for the occasion.

A reception was held also on Thursday afternoon by the Royal College of Physicians of Edinburgh in their premises in Queen-street to which the members of the Association were invited. Owing probably to the wet weather the attendance of guests was small compared to the number of invitations which had been issued. It had been arranged that after being received in the College the visitors should adjourn to the gardens opposite the building and enjoy the band and pipe music to be provided, but the weather caused this part of the programme to be departed from. The guests were received in the hall by the President, Sir John Batty Tuke. On the same afternoon a large number of members of the Association visited the Royal Hospital for Sick Children upon the invitation of the directors and medical staff.

Professor and Mrs. Bayley Balfour's garden party to the Association on Thursday also suffered from the effects of the weather. The host and hostess were at home from 4 till 6 o'clock at Inverleith House, within the grounds of the Royal Botanic Gardens and Arboretum, but only during an interval of half-an-hour, when the rain ceased, could the guests take an opportunity of visiting the botanic garden, the palmhouses, and the greenhouses. Over 200 ladies and gentlemen accepted Professor Balfour's kind invitation.

On Thursday afternoon a number of Sir John Struthers's old pupils met at his house in George-square to present him with an address of congratulation upon his having received the honour of knighthood. Sir John Struthers, who is President of the Section of Anatomy at the present meeting of the Association, had not been in sufficiently good health to attend the meetings, and acting under medical advice was compelled to refuse the invitation of his old pupils to a dinner in his honour.

Some 450 members and guests assembled in the Music Hall, George-street, on Thursday evening, when the annual dinner of the Association was held. The scene presented recalled that of the dinner held at the Queen's Hall, Langham-place, when the British Medical Association met in London in 1895, but on the present occasion the addition of scenery to the elaborate arboreal decorations which characterised the London gathering increased the effectiveness of this artistic treatment of the hall. The organ was screened off by a scene representing Edinburgh Castle, with the Argyll Tower in the foreground, whilst the back-gallery was transformed into a rural landscape. Professor Sir Thomas Grainger Stewart, the President of the Association, occupied the chair and he was supported on his right by Lord Provost Mitchell Thompson, the President of the Council (Dr. Saundby), Sir William Broadbent, the President of the Royal College of Physicians of Edinburgh (Sir J. Batty Tuke), Dr. Roddick, Montreal (ex-president of the Association), Professor Bowditch, Professor Osler, the Lyon King of Arms (Mr. J. Balfour Paul), Fleet-Surgeon Corrie, the Rev. Dr. Whyte, Colonel Rooney (principal medical officer on the Scottish Military Headquarters Staff), Dr. Constantine Holman, Professor Snellen, Dr. Henry Barnes, Professor Morisani, Professor Simpson, Professor Kocher, Sir William Stokes, and Mr. Bryant; while on his left were General Chapman, Sir William Priestley, M.P., Dr. Ward Cousins, Professor Chiene, Professor T. R. Fraser, Professor Gerhardt, Dr. F. T. Roberts, Dr. Howard Kelly, Professor Blanchard, Dr. Farquharson, M.P., the Rev. Dr. Blair, Dunblane; Mr. Macnamara, Professor Doyen, Mr. Wheelhouse, Professor Rosenstein, Sir Charles A. Cameron, Sir Andrew M'Donald, Professor Sir Henry Littlejohn, Professor Boeck, and Dr. Dawson Williams. The toast of "The Queen" was received with enthusiasm as was that also of "The Prince and Princess of Wales and the Royal Family," both proposed by the President, who said that everyone must sympathise most cordially with the Prince of Wales in the trying circumstances in which he was now placed. "The Navy and Army" was next on the list and in proposing the toast the President said that our navy had done so much for us, it kept us so safe, it grew so wonderfully, and it had such an amount of power of work in it, that all felt as secure as any nation could do which had to depend upon defences of that sort against possible enemies. They had present as a representative of the navy one of their own profession, Fleet-Surgeon Corrie, who had sailed under the Queen's flag in every clime and had served in every possible way. The army had done a good many things in its time and they were honoured that night with the presence of a distinguished officer, the officer commanding the army in Scotland, who from his long experience knew something about warfare and army organisation. Fleet-Surgeon Alfred Corrie, R.N., and General Chapman having briefly replied, Dr. Roddick (Montreal) proposed "The Lord Provost, Magistrates, and Town Council of Edinburgh," coupled with the name of the Lord Provost, who, in his reply, said that Dr. Roddick had alluded to Edinburgh having taken the lead (if he might put it in that way) in regard to the care of public health. For that distinction they were indebted to two gentlemen. First, his friend Sir Henry Littlejohn, who had been for many years medical officer of health; and secondly, the convener of the Public Health

Digitized by Google

Committee, Bailie Pollard, who had been spoken of as an expert in the care of public health. He (the speaker) had no doubt that when the Association did them the honour to come back again to Edinburgh they would see in full operation a hospital for the treatment of infectious diseases second to none in the kingdom. Professor F. T. Roberts proposed "The Houses of Parliament," which was responded to by Sir William Priestley, M.P. The toast of the evening, "The British Medical Association," was proposed by Professor Bowditch, Harvard College, Boston, U.S.A. The fact that an American should have been selected to propose this toast he regarded with peculiar satisfaction, because it suggested a subject so much in their minds and on their tongues—the essential unity of the two nations. It was no new proposition to say that in all essential matters the interests of the English-speaking races were identical all over the world. This had been accentuated during the last few months owing to the war now rapidly approaching a termination and nothing had given him more satisfaction than to see the thorough appreciation of the gallant deeds of the American navy by everybody on this side of the Atlantic. The sentiment in America was as warm as it was in this country. There was a Continental Anglo-American Medical Association composed of medical practitioners from America and England practising in the cities of northern Europe and Africa, and this was another way in which nations might combine for common purposes. This Anglo-American idea was capable of being indefinitely extended. It was a plant which could be cultivated and he had no doubt it would be cultivated and would bear fruit in various directions. He saw no reason why they should not have an Anglo-American standard of medical education. A great deal might be done in this way and he commended the thought to the Association as the guardians of medical education. Dr. Saundby, President of the Council, in his reply said that with reference to what Professor Bowditch had remarked about Anglo-American relations he was sure they all reciprocated most fully what that gentleman had said, but he was not at all sure that anything like a really formal acknowledgment of American education and American degrees was, at the present time at any rate, within the range of practical politics. They had to thank the Lord Provost for his kindness in welcoming them to the city, in gracing by his presence their various meetings, and in showing them such splendid hospitality. They had also to thank the University for having placed its buildings at their disposal; the Royal Colleges of Physicians and Surgeons for the hospitality they had shown; and the local profession, and especially those gentlemen who had held office in the Executive Committee and as secretaries, for the work they had done in organising the present splendid meeting, which was certainly one of the very best meetings which it had been his privilege to attend—he would almost say one of the best meetings in the history of the Association. Professor Osler (Baltimore) gave the toast of "The President," who, he said, was a gentleman worthy of Edinburgh, worthy of the profession of a great Empire, and worthy to control the destinies of that great Association. The President having replied Professor Chiene proposed the toast of "The Guests." Professor Gerhardt (Berlin), Professor Howard Kelly (Baltimore), Professor Blanchard (Paris), and Professor Kocher (Berne) responded. The proceedings terminated with the singing of "Auld Lang Syne" shortly before the clock chimed the hour of 12.

In the rooms of the Royal College of Physicians of Edinburgh a reception and conversazione was given on Thursday night by the local Ladies' Committee. There was a great gathering of ladies and gentlemen in response to the 2000 invitations which had been issued. The company were received by Lady Grainger Stewart and Mrs. Argyll Robertson, the conveners, and Mrs. Underhill, the honorary secretary of the Ladies' Committee. The rooms, corridors, and staircases were decorated with palms and evergreens and coloured lights were hung among the trees skirting the upper walk of the eastern portion of Queen-street Garden. Music was supplied by Mr. Dambmann's band and a vocal concert was provided at which Miss Macdougal, Miss Pyatt, Mr. A. Bach and others assisted. This concert was held in Queen-street Hall.

The principal function on Friday, a much more fortunate day in respect of weather than Thursday, was the garden party at Hopetoun House given by the Earl and Countess of Hopetoun. A thousand invitations were issued to members of the Association and a thousand to the neighbouring gentry and military garrison and to the leading citizens of Edinburgh. A number of the guests went from Edinburgh by the North British Railway to Dalmeny and drove thence to Hopetoun House, but the greater part of the members of the Association drove the whole way and in so doing enjoyed an ever-changing series of splendid views. The gardens of Hopetoun House were looking their best and the splendid views of the Forth, combined with the warm reception of Lord and Lady Hopetoun, worked together to make the garden party a most pleasurable experience for all.

On the invitation of the President and Council of the Society of Scottish Artists a conversazione was held on Friday afternoon in the exhibition rooms of the society, 18, George-street, when a large number of members of the Association and others were present. Mr. James Cadenhead, R.S.W., chairman of the Council of the Society, received the guests.

Through the kindness of Dr. J. Cossar Ewart, Regius Professor of Natural History in the University of Edinburgh, 100 of the members of the Association spent a pleasant and instructive afternoon at Penicuik on Friday, July 29th. The party leaving the Waverley Station by special train at 2 P.M., arrived half an hour later at Penicuik, where they were met by Dr. Badger, medical officer of the burgh, and by him were conducted to The Bungalow, Professor Ewart's house. The visitors were first shown Professor Ewart's photographs bearing on the experiments which he has carried on at The Bungalow during the past four years. These included photographs of Matoppo, the Burchell zebra, whose progeny, Romulus, is believed to be the first cross obtained between an ordinary mare and a zebra stallion. Numerous photographs of the hybrid zebras were shown, as was also a valuable series of the embryos secured by Professor Ewart in the course of his investigations into the development of the skeleton of the limbs of the horse. Proceeding to the lawn the visitors found ranged round it cages containing pigeons, rabbits, dogs, &c., in evidence of the changes produced by cross-breeding. They then proceeded to the quadrangle at the rear of The Bungalow and saw all the horses and zebra hybrids in the extensive stud, while Professor Ewart gave a detailed account of his experiments. This was a very delightful afternoon for all.

The last festivity in connexion with the British Medical Association meeting at Edinburgh was a ball given in honour of the Association by the Edinburgh Corporation. The Corporation had no hall large enough to hold all the members of the Association, but the officials did their best in the circumstances to distribute the tickets at their disposal impartially and those who were present—and they numbered over 800 of the members—enjoyed a very pleasant

Digitized by Google

evening. About 400 citizens had been invited, chiefly those who have been the hosts of the visitors during the week. The reception of the guests began at half-past eight o'clock by Lord Provost Mitchell Thomson and Mrs. Mitchell Thomson. With them, in their robes of office, were Sir James Russell, Bailies Mackenzie, Hay, Steel, Gulland, and ex-Bailies Dunlop, Grieve, and Gray. The hour was somewhat early and the guests at first came very slowly; but after the official reception was over and the dancing had commenced the Lord Provost and Mrs. Mitchell Thomson received the late comers in a less formal fashion under the gallery. Dancing was carried on simultaneously in the Music Hall and Assembly Rooms and was continued with spirit until early on Saturday morning. Two Scotch reels were danced to the edification of lowland and foreign visitors.

The summer graduation ceremonial of the University of Edinburgh took place on Saturday, July 30th, in the M'Ewan Hall, in the presence of most of the members of the British Medical Association, who had attended the meeting just concluded. Principal Sir William Muir presided and he was accompanied to the platform by Sir William Priestley, M.P. for the University, Lord Provost Mitchell Thomson, Lord Pearson, and a large representation of the Senatus Academicus. The honorary degree of LL.D. was conferred upon the following gentlemen among others: Dr. H. Pickering Bowditch, Professor of Physiology in Harvard University; Sir William Broadbent, M.D., F.R.S.; Dr. Lauder Brunton, F.R.S.; Dr. Eugene Doyen of Paris; Dr. David Ferrier, F.R.S.; Dr. Joseph Forster, Professor of Hygiene and Bacteriology in the University of Strassburg; Dr. Carl Gerhardt, Professor of Medicine in the University of Berlin; Mr. Hutchinson, F.R.S.; Dr. Theodor Kocher, Professor of Surgery in the University of Berne; Dr. August Martin, Professor of Gynæcology in the University of Berlin; Dr. Johann Miculicz, Professor of Surgery in the University of Breslau; Dr. Morisani, Professor of Midwifery in the University of Naples; Dr. William Osler, F.R.S., Professor of Medicine in the Johns Hopkins University, Baltimore; Dr. William S. Playfair; Dr. Thomas Roddick, Professor of Surgery in the M'Gill University of Montreal, ex-President of the British Medical Association; Dr. Siegmund Rosenstein, Professor of Clinical Medicine in the University of Leyden; Dr. Herman Snellen, Professor of Ophthalmology in the University of Utrecht; and Sir Richard Thorne Thorne, F.R.S. A number of graduates had conferred upon them the degrees of M.A., D.Sc., M.D., and M.B. The address to the graduates was delivered by Professor Bayley Balfour.

THE GENERAL MEETINGS.

THE THIRD GENERAL MEETING.

The third general meeting was held on Thursday afternoon, July 28th, in the M'Ewan Hall, under the presidency of Sir THOMAS GRAINGER STEWART.

Dr. SAUNDBY, President of the Council, announced that the Section of Tropical Diseases had asked the Council to bring before the general meeting the desirability of petitioning Government to send an expert pathologist to South Africa to investigate black-water fever. He moved that the general meeting should make a representation to Government to that effect.

Professor CHIENE seconded and the motion was agreed to.

Professor ANNANDALE then delivered the Address in Surgery which was published in our columns last week.

Mr. BRYANT, in moving a vote of thanks to Professor Annandale for his address, expressed his warm approval of the observations upon the moral aspect of the profession.

Professor BENNETT, in seconding the vote, spoke of the debt which the medical profession were under to Professor Annandale not only for his excellent address, but also for his surgical and pathological writings and for the beautiful series of examples of injuries to the elbow-joint which he had laid before the Association.

The vote of thanks, which was heartily accorded, was acknowledged by Professor ANNANDALE in a few words.

THE CONCLUDING GENERAL MEETING.

The fourth and concluding general meeting of the Association was held on Friday morning, July 29th, in the M'Ewan Hall, under the presidency of Sir THOMAS GRAINGER STEWART.

Sir JOHN BATTY TUKE, who was received with applause, delivered the Address in Psychological Medicine, which will be found printed in another part of this issue of THE LANCET.

At the close of Sir John Batty Tuke's eloquent and learned address, Dr. BLANDFORD proposed a vote of thanks to him, which was seconded by Professor MCDONALD of New York, who called attention amidst applause to the good feeling now existent and growing between his country and the mother-country.

The vote of thanks was passed unanimously.

Dr. SAUNDBY, the President of the Council, then proposed that the hearty thanks of the Association should be tendered to the Lord Provost, Magistrates, and Council of Edinburgh for the hearty welcome accorded to the Association; to the Lord Provost and Mrs. Mitchell Thomson for their reception in the Museum of Science and Art; to the Dean of the Chapel Royal for permission to hold Divine service in St. Giles's Cathedral; to Dr. Whyte for his sermon, and to Dr. Blair for his assistance in the service; to the University Court for the use of the splendid buildings of Edinburgh University; to the Senatus Academicus, to the Royal College of Physicians and Surgeons, Edinburgh, to the Royal Medical Society, to Lady Grainger Stewart, to the Duke of Buccleuch, to the Marquis of Bute, to the Earl of Hopetoun, and to the others who had entertained the members; to the managers of the Royal Infirmary and various hospitals for opening their institutions; to the committee of the Masson Hall and to the various clubs and to the Philosophical Institution and other bodies which had given the use of their premises to the Association; to the members of local branches of the Association for their hospitality; to the medical faculty of the University of St. Andrews; to the presidents of sections; to the chairmen and honorary secretaries of committees for their successful arrangements; to Dr. R. W. Philip and Mr. J. Shaw M'Laren, the local secretaries; to Dr. C. E. Underhill and Dr. P. A. Young, the treasurers, for their successful labours; and to their distinguished foreign visitors for their presence.

Dr. P. M. DEAS seconded and the resolution was agreed to unanimously and enthusiastically.

Dr. SAUNDBY then proposed a vote of thanks to Sir Thomas Grainger Stewart for the admirable manner in which he had presided over the session of the Association now drawing to a close.

This was seconded by Dr. HENRY BARNES, the President of the Association two years ago, who spoke of Sir Thomas Grainger Stewart as having "furnished by his example one of the greatest incentives to progress in medical study that any one could have," and who desired to include the name of Lady Grainger Stewart in the vote of thanks.

The vote was carried by acclamation.

Sir THOMAS GRAINGER STEWART replied in a few modest words, in which he attributed any success in administration to "those splendid fellows who had put their shoulders to the wheel and done the work," the honorary secretaries.

The meeting then terminated.

THE SECTIONS.

MEDICINE.

THURSDAY, JULY 28TH.

The Open-air Treatment of Phthisis.

A paper on this subject had been read and patients exhibited at the meeting on Wednesday by Dr. CAVERHILL, but the discussion on the matter had been adjourned until to-day.

Dr. CALWELL (Belfast) thought that the treatment of phthisis might be preventive and curative. The former we now know but do not sufficiently practise. No drug was specific, whereas, on the other hand, the open-air treatment, if carried out long enough, infallibly restored to health unless

Digitized by Google

the cases at the outset were too far advanced. This treatment should be carried out in its entirety or left alone, without temporising, and it was far better done away from friends, who interfered too much. It consisted of continuous living in open-air night and day, great attention to diet, exercise regulated to the needs of the different cases, watching the temperature and pulse of the patient, absence of furniture in the room and anything else which could catch dust or diminish the cubic space.

Dr. BERNARD J. GUILLEMARD (Cape Colony) narrated his experience in South Africa on the high lands in the interior. The soil was sandstone. The winter season was perfect and the results of treatment were very satisfactory.

Dr. P. SIDNEY JONES (New South Wales) confirmed the advantages to be derived from South Africa. He also wished to draw attention to the value of the Australian climates. In both of these places the climate in different parts differed very greatly and physicians who sent patients out should bear this in mind.

Miss JANE WALKER, M.D. Brux. (London), had tried the open-air treatment of phthisis on a farm in Norfolk and had found the conditions there very satisfactory. She thought it unnecessary to go so far away from home.

Dr. BEZLY THORNE (London) spoke to the advantage of open-air treatment, mentioning Falkenstein as a favourite locality, but he wished to confirm the remarks of the previous speaker. He mentioned the case of a young woman in an advanced stage of phthisis who was, however, so reduced in circumstances as to be unable to go abroad. She spent all her time in Kensington-gardens in all weathers, lived with the window open night and day, took plenty of exercise and food, and in the course of six months was quite well again.

Dr. W. DENTON JOHNS (Bournemouth) thought that many cases might be treated just as well at home if we could only enforce discipline, diet, &c., and control the friends.

Dr. H. J. CAMPBELL (Bradford) thought the great source of fallacy lay in selecting the appropriate place for the particular case, both as to its variety and stage, and the coöperation of the local physician was much needed in this respect.

Mr. FREDERICK CHURCHILL (London) indicated by means of drawings what structural arrangements he thought should exist at all our south coast watering-places for the treatment of such invalids.

The Significance and Consequences of Different States of Vascular Tension with their General Management.

Sir WILLIAM BROADBENT (London), in opening this discussion, said he thought it wise to limit the debate to arterial tension—i.e., arterial blood-pressure, excluding the venous system. Nor did he propose to touch on the question of testing blood-pressure by different instruments. Vascular tension essentially depends on the force and quantity of blood delivered at each systole of the heart and also on the resistance in the small vessels—i.e., the peripheral resistance. Owing to the size of these, capillary attraction and the friction of their walls are important factors. The pulse is our means of estimating vascular tension, and about this there are four points to note:—(1) the size of the vessel, which varies in some individuals at different times and widely in different individuals; (2) the state of the artery between the beats—whether it is full and round or collapsing and flat; this is the best test of the state of the peripheral resistance; (3) the character of the rise of each stroke (the aortic wave) whether short and gradual or high and sudden; and (4) the degree of pressure required to obliterate the vessel and stop the pulse. Turning first to low vascular pressure, its causes and significance, it may be noted that low tension is often found in long-lived persons who will tell us, perhaps, that they always had a weak heart. But in all cases it is necessary to examine the heart as well as the pulse. Lowered vascular tension is also met with in fever and it may be the chief cause of the lowered nutrition, there being not sufficient pressure in the capillaries to ensure nutrient fluid exuding. Lower vascular tension is often associated with neurasthenia and is also met with in other conditions of debility. It is met with in epilepsy and may be one of the factors in the production of fits. Turning, on the other hand, to conditions of high arterial tension, it is to be remembered that this often runs in families and may then be found under these circumstances in very young persons. The effects of continuous high arterial tension are very important and include hypertrophy or dilatation of the heart, dilatation of the aorta, atheroma of the walls of the aorta and large vessels, fibroid condition of the heart, and thickening of the valves. Variations in vascular pressure are of universal application in all kinds of disease. In neurasthenia, for example, the speaker had always more hope of a case when the vascular tension was high, for in such cases it is possible for the impurity of the blood, which is the cause of neurasthenia, to be eliminated. It was in cases such as these that a dose of blue pill changed the whole aspect of the world. In melancholic conditions the vascular tension was usually high; in maniacal conditions it was usually low. If this fact be borne in mind it helps us to understand how it is that sometimes morphia increases maniacal conditions instead of producing sleep, by lowering vascular tension. Attention to the arterial tension will often enable us to foresee such untoward effects. In epilepsy we find the two extremes of vascular tension are associated with the convulsions; when the tension is low the prognosis is less favourable, because the fits are then less dependent on the vascular condition. Uræmic convulsions are directly associated with high blood-pressure and not the uræmic poisons in the blood. Convulsions occur in high arterial tension from other causes. In many cases of gouty bronchitis, recurrent attacks of bronchitis in a gouty subject are usually attended by a pulse of high tension, and consequently the treatment of these cases is more successful by eliminants than by climatic treatment. As regards Cheyne-Stokes respiration the speaker had never seen it without high vascular tension. By some this symptom has been attributed to irritation of the respiratory centre or the cerebral hemispheres, yet, strange to say, a patient may go on with his business while the symptom continues for months. But in the speaker's opinion it was usually associated with high tension and he had more than once been able to observe a direct association. Cheyne-Stokes respiration must not be confused with "cerebral respiration," in which there was a complete cessation of breathing and then a sudden start after an interval. Turning to the general management of variations of blood-pressure Sir William Broadbent first considered states of low tension. The essential origin of the condition must be ascertained, whether it be some vice of nutrition, some digestive derangement, or perhaps the absence of some internal glandular secretion, especially the suprarenal. In this connexion it had recently been shown that cancer may cause death by some toxin it secretes. The drugs most useful here are digitalis and caffein, which help by their diuretic action to eliminate. The chief cause of high tension is some toxic condition of the blood, which must be eliminated. Here diaphoretics, moderate exercises, baths, diuretics, and purgatives are useful. He attached the greatest importance to mercury. Other purgatives, dose for dose, were not nearly so valuable as calomel, which seemed to have almost a specific action. As regards the contra-indication of mercury in albuminuria he believed the old superstition was now quite exploded. At any rate, it was a fact that uræmic convulsions could be averted by calomel. Nitro-glycerine and erythrol tetranitrate were useful when other measures were inapplicable.

Professor J. B. BRADBURY (Cambridge) said that the question which interested him most was the general management of vascular conditions. This naturally raised the previous question of their significance and effects, though it would not be necessary to consider the conditions dependent on cardiac valvular disease. Of the opposite conditions of intra-arterial blood-pressure high tension is the more important. Low tension is mainly of prognostic and therapeutic value and is dependent upon some condition apart from the blood and blood-vessels. Palpitation is the most common symptom of relaxed arteries, but in most instances this is primarily of nervous origin. The treatment of low tension is that of its cause. High tension, on the other hand, is directly dependent on blood, cardiac, or vascular conditions—to a certain extent on hereditary and nervous influences—and it is an important causal factor in disease. Certain poisons—lead, alcohol, alimentary toxins, the poisons of gout, syphilis, influenza, &c.—seem to cause an arterio-capillary contraction, intra-arterial blood-pressure is raised, and apart from immediate symptoms changes in the heart and vessels and subsequently in other tissues occur. Owing to this, the treatment of high arterial pressure becomes an important measure, and much may be done to alleviate the condition. With care the patient may even live to a good old age. Thus at present the speaker had under treatment an old lady, aged eighty-nine years, who had been under his care for about ten years. She

Digitized by Google

suffered from copious attacks of hæmatemesis when he first attended her and these gave her much relief. Latterly she had been less troubled with the "black-vomit," but had found relief from distressing head symptoms—including "word-blindness," &c.—by frequent doses of mercurials and saline aperients and a carefully-regulated diet. Her case might be regarded as a typical one of what his colleague, Professor Allbutt, had designated "senile plethora." From the point of view of treatment, cases of high arterial blood-pressure may be divided into the more or less curable and the incurable. In some conditions—e.g., pregnancy—it is merely temporary and passes away with this condition. In anæmia it is quite curable, but this is not so in other diseases. In these cases, especially after middle age, pathological changes occurred in the arteries (and other tissues), and these changes tend to keep up the high arterial pressure. In old people where the arterio-sclerosis is extreme complete cure cannot result. All grades of high arterial tension occur and in all some improvement may be expected. The essential object in the majority of cases is to rid the blood of its toxic substances, to prevent their reaccumulation, to keep down the arterial blood-pressure by careful dieting, judicious medicinal treatment, and moderate daily exercise. Potassium iodide and purgatives, mercurial and saline, are extremely useful, but often they are insufficient, especially if immediate relief—as when pain, dyspnœa, &c., are present (symptoms for which the patient usually seeks advice)—is required. Here vaso-dilating drugs are necessary, and amyl-nitrite, nitro-glycerine, chloroform, or, when a long-continued action is required, erythrol tetra-nitrate may be used. The last is especially adapted to those cases in which pain is not severe but of long duration, or in warding off expected attacks for a time—cases such as the speaker quoted in detail. A man, aged sixty-two years, complained much of oppression behind the sternum. There was no history of gout, but he had had intermittent fever and lumbago and tonsillitis. There was no cardiac bruit, but marked increased arterial tension. The condition had existed for about six months. The appetite was good, the bowels were costive, and he slept fairly well. The attacks usually came on in the early morning and lasted for about five minutes. Erythrol tetra-nitrate (1 gr.) gave great relief, nitro-glycerine very little. A course of blue pill and later potassium iodide with occasional purgatives was enjoined; but although considerable improvement occurred erythrol tetra-nitrate had constantly to be taken to ward off the attacks, which it did most effectually if taken the last thing at night. In the *British Medical Journal* of April 10th, 1897, the speaker had described a case of angina pectoris which erythrol tetra-nitrate (1 gr. every 4 hours) kept at bay. This patient also tried mannitol hexanitrate in 3 gr. tabloids at 10 A.M. and at 2 P.M. and 6 P.M., but the effect was not so satisfactory as with the erythrol tetra-nitrate. In fact, the patient at once gave it up for the latter drug. An interesting case simulating Raynaud's disease had recently come under his notice. This case was of interest as M. Huchard had endeavoured to show that spasm of the arterioles producing arterial hypertension is an early phenomenon of arterio-sclerosis and that it often long precedes the material lesion properly so-called. Dr. Duncan had sent to the speaker notes of a case of interstitial nephritis with uræmia in which he believed the patient's life was saved by erythrol tetra-nitrate. There were œdema of the lungs with very distressing dyspnœa and Cheyne-Stokes respiration, very high tension pulse, most irregular action of the heart, insomnia (in spite of hyoscine hydrobromide given hypodermically up to $\frac{1}{75}$ gr.) practically for six days—with the exception of fifteen or twenty minutes in each twenty-four hours—scanty urine and (for the two nights previously to taking the erythrol) delirium. Dr. Duncan had written on July 11th: "The patient a fortnight ago yesterday—i.e., June 26th—was apparently moribund, but erythrol tetra-nitrate was given as a last resource. The effect it had was really marvellous and the patient has steadily improved every day, so much so that on Saturday, July 9th, he was able to go downstairs. The pulse is now quite regular and soft, the œdema of the lungs has disappeared, and the amount of urine has greatly increased, amounting to nearly 80 oz. on some days." Charts were exhibited showing the comparative physiological action of several vaso-dilators.

Dr. T. D. SAVILL (London) wished to draw attention to what he regarded as far the most important and serious consequence of persistent high tension. In the years 1887–88 he was first struck by the much greater thickness of the arteries in some bodies than in others in the post-mortem room, especially in aged persons, and upon further investigating these cases he found that they had suffered from symptoms of high arterial tension during life. The increased thickness was mainly due to an increase in the middle or muscular coat—i.e., the functionally active part of the arterial system. He had proposed the provisional title "arterial hypermyotrophy" for the condition, and its frequency was evidenced by the fact that out of about 280 necropsies he had made during 18 months in 1891–92 he had found 39 marked cases (14 per cent.) of the condition without counting slighter cases. These cases had all revealed symptoms of high arterial tension in their past histories and there was no doubt it was the consequence of this. The majority of these 39 cases had been free from renal disease. Microscopic sections and photographs were shown and it was pointed out that the change was a true hypertrophy, though this hypertrophy might or might not be accompanied by senile changes such as atheroma, endocarditis, &c. A granular condition with swelling of the fibres was a very constant senile change, but the essential lesion was a true numerical increase in the fibres of the middle coat, and it was an illustration of the physiological law that increased function leads to increased growth. The condition "arterial hypermyotrophy" which he had discovered in the deadhouse corresponded with a clinical condition which Professor Clifford Allbutt had described under the name "senile hyperpiesis" or senile plethora. The disease could be recognised during life by symptoms he had already described.[1] "Senile vertigo" and "senile syncope" with headache and the thickened elastic cord-like feel of the arteries were the characteristic symptoms, and it was extremely important to recognise it in persons of advancing life, for these patients had perpetual high tension and were liable to apoplexy and other hæmorrhages, which could be prevented by timely treatment.

Dr. WATSON WILLIAMS (Bristol) thought that high arterial tension was not always to be regarded as pathological and evil in its consequences. Sometimes it represented a physiological effort to meet a temporary difficulty in the system and undoubtedly in renal disease it had a favourable prognosis.

Dr. DAVID DRUMMOND (Newcastle) adverted to the low arterial tension of longevity and the importance of low tension for health. He could not agree with Sir William Broadbent that Cheyne-Stokes respiration was always associated with high arterial tension and he mentioned several cases in point.

Dr. ALEXANDER HAIG (London) asked if the time had not come when the right name could be given to the toxin which caused high arterial tension—viz., uric acid. His own case was a case in point, for he used formerly to suffer severely from headaches and all the symptoms of high tension until he had discovered that uric acid was at the bottom of it and that by controlling this he could regulate his arterial tension and so procure relief.

Dr. HANDFORD (Nottingham), Dr. SAMWAYS (Mentone), Dr. TYSON (Folkestone), and Dr. HADDON (Denholm) also took part in the discussion.

In reply Sir WILLIAM BROADBENT said he was quite prepared to admit the value of high tension in some conditions. In renal disease, for instance, low arterial tension greatly added to the gravity of the prognosis. He had always regarded (with Dr. Haig) uric acid as a cause of high tension, but only one of the causes—there were many others. He mentioned a case of epilepsy which had been sent to him by Mr. Horace Sworder in which the fits disappeared when appropriate changes were made in the diet, showing the association of high tension, uric acid, and fits. He confirmed the value of erythrol tetra-nitrate so far as his experience went.

Dr. DAVID DRUMMOND (Newcastle) read a paper on two cases of

Ether-pneumonia.

which he had observed. Cases of death after operation were, he thought, often attributed to sepsis which were really due to pneumonia started by ether. He narrated a case in which, under ether, the operation lasted one hour. It was attended by severe cough and next day the temperature rose to 102°F., and the following day there was dulness at the bases which spread upwards. The patient gradually became somnolent

[1] Brit. Med. Jour., Jan. 23rd, 1897.

Digitized by Google

and died in a few days. At the necropsy the right lung presented intense engorgement and œdema with consolidation below. There was a large excess of red blood cells in the alveoli. As to causation of ether-pneumonia, some had thought it microbic in origin, but he (the speaker) thought the ether was the sole cause. Previous pulmonary disease was a predisposing cause and it seemed more likely to arise after abdominal operations. Anders gave 1 in 3000 cases of ether administrations, but Dr. Drummond thought the disease was more frequent than this.

Dr. PARSONS (Dublin) read a paper on Some Remarkable cases of Obstruction of the Vena Cava and the other large Systemic Veins, illustrated by excellent lantern slides.

Dr. WILLIAM EWART (London) read a paper on the Treatment of Renal Diseases by means of massage and bandaging, careful diet, and medicine directed to supporting the heart.

Dr. J. STRACHAN (Dollar) read a paper on the Alcoholic Neurosis.

SURGERY.

THURSDAY, JULY 28TH.

Dr. DAVID NEWMAN (Glasgow) opened a discussion on

The Origin, Effects, and Treatment of Septic Infection of the Urinary Tract.

He commenced by saying that the subject was a very large one and therefore he intended to confine his remarks to the kidney. There are many conditions in the kidney, such as tuberculosis, which are not in themselves suppurative, but which suppurate later from pyogenic infection. These were not to be considered, but he would speak only of the conditions of the kidney which were strictly septic. The septic state of the kidney may arise through the blood-stream, "purulent embolic nephritis," or by the lymph-stream, "purulent interstitial nephritis," or there may be an "acute septic nephritis without suppuration." Here, again, the infection is through the lymph or the infection may come by the ureter and may cause a pyelitis or a pyelo-nephritis. The body has great power of resistance against infection and this is very noticeable in the bladder, and mere retention of urine or mere injection into the bladder of a "culture" will not cause cystitis, but if the two occur together then cystitis may result. The peculiar distribution of the lymphatics in the walls of the bladder, ureter, and kidney render it easy for septic infection to spread from the bladder to the kidney without the occurrence of any sepsis in the ureter itself. The chief point in treatment is prophylaxis, for we can do much more to prevent sepsis of the kidney than we can do to cure it.

Dr. T. ROVSING (Copenhagen) stated that there are two groups of bacteria which affect the urinary tract: (*a*) those which decompose the urea—namely, staphylococcus pyogenes aureus, staphylococcus pyogenes albus, proteus Hauser, and diplococci and bacilli, some of which are pyogenic and others not; and (*b*) those which do not decompose the urea, such as bacillus coli. In cases of bacteruria, in which the urine may swarm with bacteria and yet no cystitis be present, the microbe which predominates is the bacillus coli and the urine is acid, but in cases in which cystitis is present we have almost always to do with microbes which can decompose urea, such as the staphylococcus aureus. In cases of cystitis, in which both bacilli coli and urea decomposing microbes are present, treatment with nitrate of silver will cure the cystitis and the urea decomposing microbes will disappear, but the bacilli coli will remain. The importance and frequency of the bacilli coli have been over-estimated chiefly because by rapid growth they may hide the real pathogenic microbes. As to treatment, prevention is of the chief importance, and as it is impossible to sterilise the urethra the microbes which are necessarily introduced with every instrument must be killed and that is best done by injection of 50 c.c. of a 2 per cent. solution of nitrate of silver after every operation.

Mr. MANSELL MOULLIN (London) pointed out that males were less easily affected than females by sepsis from the exterior, but that they were also less easily treated. Rigors after any urethral or vesical operation were always a sign of absorption of bacterial toxins. He was inclined to ascribe much greater importance to the bacillus coli than did Dr. Rovsing.

Dr. M. MELCHIOR'S (Copenhagen) contribution to the discussion was a report on 50 cases of Septic Infection of the Urinary Tract with Bacteriological Examination. He considered that bacillus coli was by far the most frequent microbe in cystitis. In most cases it was introduced by means of instruments; all the five patients who had had no instrument passed were women. He was of opinion that the bacillus coli was also the most frequent cause of pyelitis and suppurative nephritis.

Mr. BRUCE CLARK (London) laid it down as essential that the mucous membrane of the urinary tract must be abraded or otherwise impaired before any micro-organism could set up an inflammation. He was inclined to think that in most cases cocci were the first to appear and that these were replaced in time by bacilli coli, and he quoted some experiments by Dr. Klein which showed that in a series of inoculation cases of peritonitis the bacilli prodigiosi of the first experiment was replaced by bacilli coli in the later. He considered that the marked and permanent contraction of the bladder which was found in cases of prostatitis was due to a streptococcic infection of the bladder wall with consequent formation of fibrous tissue.

Mr. W. H. BATTLE (London) related the particulars of three cases of infection of the urinary tract in which a remarkable enlargement of one or both kidneys took place, evidently due to septic infection, and yet, though no operation was done on the kidney itself, the enlargement gradually disappeared and the patients recovered.

Dr. NICOLL (Glasgow) had recently made a large number of very careful bacteriological examinations and cultures in cases of urinary infection, and up to the present no definite and trustworthy results had been obtained. An important point had been discovered, and that was that acid, neutral, and alkaline media had to be employed before any statement could be made as to the micro-organisms present. He was inclined to think that no known method existed of distinguishing the gonococcus from other forms.

Dr. D. MACEWAN (Dundee) said that it was most important in women to render aseptic the meatus urinarius before introducing any instrument. In all cases in which urinary sepsis was present regular and complete evacuation of the bladder was most important. Boric acid, the benzoates, salol, and methylene blue might be given by the mouth, and locally boric acid, nitrate of silver, and perchloride of mercury were the best antiseptics.

Professor KOCHER (Berne) was inclined to attribute more importance to the bacillus coli than Dr. Rovsing would allow.

Sir WILLIAM STOKES (Dublin) read a paper on a case of Exophthalmic Goitre Treated by Thyroidectomy. He had removed a portion of the enlarged thyroid gland in a case of marked Graves's disease and the result had been a complete recovery; the dyspnœa, palpitation, and exophthalmos had all disappeared. He then discussed the pathology of the disease and showed that the "toxin" theory was the only one admissible.

Professor KOCHER (Berne) complimented Sir William Stokes on the result of his case and remarked that the results were not always so good; he had operated on about 50 cases of exophthalmic goitre. He advised complete excision of one lobe and of half or two-thirds of the other. He spoke strongly against using either ether or chloroform in thyroidectomy and urged that only cocaine should be used.

Dr. L. CASPAR (Berlin) read a paper on Catheterism of the Ureters in Both Sexes. He thought that with care there was very little risk of injury, but that there was some risk of infection. He said that it should only be used in diagnosis or treatment when the ordinary measures failed.

Mr. EDMUND OWEN (London) read a paper on the Treatment of Cleft Palate. He pointed out the importance of making the mouth as aseptic as possible and advised that if the tonsils were enlarged or adenoids were present these should be treated at least ten days before the operation on the palate. A modified Smith's gag was exhibited and he recommended the position with the head hanging over the end of the table as the best; he preferred to have the child only slightly under the influence of the anæsthetic.

Dr. M. MELCHIOR (Copenhagen) operated on a girl, aged sixteen years, for a large sarcomatous growth at the back of the neck; it was found impossible to remove it, but by repeated electrolysis at a later date the whole of the growth sloughed away and no return had taken place though the operation was performed three years ago. 500 milliampères for five minutes was the best method and of course the patient was anæsthetised.

Digitized by Google

Mr. STANLEY BOYD (London) doubted the value of the method unless it possessed a selective power over the malignant growth; this was perhaps the case.

Mr. A. NEVE (Kashmir) pointed out that in India the death-rate from chloroform was only about 1 in 8000 at the most and in one collection of 100,000 cases no death had occurred. This he attributed chiefly to the high temperature in India and he especially urged the importance of not piling on chloroform during struggling. At his suggestion the Section passed a resolution asking the Indian Government to publish yearly the statistics of cases of administration of chloroform and the deaths therefrom.

Mr. C. YELVERTON PEARSON (Cork) read the notes of a case of a Large Spina Bifida (Meningomyelocele) which he had treated successfully by the open method. The improvement in the paralysis which had been present was marked. A point of importance in the operation was that the head must be low.

In the afternoon Mr. MITCHELL BANKS gave a lantern demonstration on Surgery, Ancient and Modern.

OBSTETRICS AND DISEASES OF WOMEN.

WEDNESDAY, JULY 27TH.

Dr. CULLINGWORTH opened a discussion on

The Surgical Treatment of Pelvic Inflammation.

Referring to his address in Obstetrics and Gynæcology at the meeting of the Association held in Newcastle in 1893 Dr. Cullingworth considered that it was no longer necessary to adduce arguments in favour of a method of treatment which, although for a time vigorously opposed, has now been generally accepted. The following points having been selected for discussion debate could be confined within useful and manageable limits—viz., (1) the indications for operative interference in pelvic inflammation; and (2) the choice of time for operation. 1. Adopting the usual classification of pelvic inflammation into pelvic cellulitis and pelvic peritonitis the former class of cases is first dealt with. In pelvic cellulitis when the inflammation is unattended with suppuration no operative interference is necessary. When an abscess is formed the ordinary rule of surgery should be followed and the pus let out as soon as it is discovered and is within reach. The opening of a cellulitic abscess should always be performed without opening the peritoneal cavity. These abscesses in the great majority of cases point on the external surface of the body. More rarely they point in the vagina. Sometimes they are formed at the back of the pelvis beneath the posterior parietal peritoneum. In that case the pus does not easily make its way to a surface and is apt to burrow. It thus may become necessary, even when the presence of pus is as yet only a matter of inference, to dissect down in the direction in which the supposed abscess is situated, commencing with an incision similar to that employed in the operation for tying the external iliac artery and carrying on the dissection from without inwards along the floor of the iliac fossa, lifting up the reflexion of peritoneum and dissecting beneath it. Circumscribed abscesses limited to the upper part of the broad ligament must be of extreme rarity, if they exist at all. Most of the cases so described have probably been examples of pyosalpinx or suppurating ovary in which the broad ligament has been drawn over the inflamed organs in the form of a hood. The indications in pelvic peritonitis cannot be stated so categorically. The personal experience of Dr. Cullingworth has led him to regard the following signs and symptoms as being strongly suggestive of the need for operative interference. (*a*) The presence of a definite, more or less fixed, irregular swelling in one or both posterior fossæ of the pelvis, larger in size than would be accounted for by the matting together of a merely thickened tube and a normal or slightly œdematous ovary, and accompanied with pain and fever. If such a swelling is found to be increasing in size in spite of rest and the local application of warmth the suspicion that pus is present in appreciable and dangerous quantity almost gives way to certainty. (*b*) The occurrence during an attack of acute inflammation of the uterine appendages of a tense globular cystic swelling in the pouch of Douglas. Whether this proves to be an intra-peritoneal abscess or a tense encysted collection of serum the indications for surgical relief are equally positive. (*c*) The outbreak of recurrent attacks of pelvic peritonitis in a patient known to have had an acute salpingitis, in whom there has remained a quiescent but obvious swelling in the posterior part of the pelvis. In such cases there is generally a pyosalpinx or an ovarian abscess. (*d*) The sudden appearance of symptoms of general septic infection in a patient with a more or less definite history of pelvic inflammation and a localised swelling above the vaginal roof. Such cases urgently need surgical intervention. They will often be found to be examples of tubo-ovarian abscess. The above are instances of suppurative inflammation of the appendages. In cases of non-suppurative inflammation gradual recovery may usually be expected to take place without operation. But operative interference is indicated even here if there is reason to suspect complications such as incipient cystic disease of the ovary, or if the circumstances of the patient being such as to render it highly important that she should be restored to health quickly, and the alternatives having been frankly explained to her, she should decide in favour of operation. 2. With regard to the choice of time for operation it is no doubt wise, in the majority of cases, to defer operation until acute symptoms of localised peritonitis have subsided. This has been adopted as a general rule of practice in the surgery of the appendix vermiformis and is equally applicable in the surgery of inflamed uterine appendages. Exceptions to this rule frequently occur, as, for example, where a rapidly increasing elastic swelling in Douglas's pouch or in the lower part of the abdomen indicates acute suppuration and again where the symptoms point to septic absorption.

Dr. E. DOYEN (Paris) laid down the following rules as a guide to intervention in the different varieties of pelvic suppuration. First (extra-peritoneal suppuration), phlegmon of the broad ligament: (*a*) by iliac evolution—classical iliac incision; (*b*) abscess of the inferior portion of the broad ligament—lateral colpotomy. Secondly (intra-peritoneal suppuration): (*a*) the inflammatory mass remains intra-pelvic and does not reach the brim—vaginal operation; (*b*) the suppurating tumours pass the brim of the pelvis and reach the level of the umbilicus—laparotomy. By each one of the above methods, vaginal or abdominal, three distinct operations may be performed: (1) simple incision of the purulent focus; (2) ablation of the annexa, leaving the uterus; and (3) total castration.

Dr. JACOBS (Brussels) made some observations based on an experience of 713 operations. In cases of bilateral disease of the appendages he thought that the vaginal route should be chosen in cases of old-standing pelvic suppuration, with fistula adhesions, peri-uterine abscess, &c., whilst the abdominal way was preferable in relatively recent cases in which there was no evidence of injury to surrounding organs. Operating on these lines he had had the following results:—vaginal route—432 cases, 424 cures, and 8 deaths; abdominal route—98 cases, 95 cures, and 3 deaths. Although all suppurative inflammations were of infectious origin it was seldom that the pus was very virulent at the time of operation and it was of less virulence in proportion as the case was of longer standing.

Dr. LANDAU (Berlin) contributed to the discussion a paper on

Vaginal Cœliotomy

based on 58 cases operated on during the last three and a half years. All the patients recovered. He concluded from his experience that those patients who were operated upon by vaginal cœliotomy for true, genuine—not inflammatory—tumours and for extra-uterine pregnancy without severe inflammatory symptoms had been permanently cured. On the other hand, of the patients in whom inflammatory conditions led to the operation only 20 per cent. at best had been cured. This was generally due to the operation being performed when the indications were against it and in most cases the vaginal radical operation should have been performed. As regards the choice between the vaginal and abdominal route there was much in favour of the former. He dwelt briefly on the technique involved, but for full particulars he referred his hearers to the translation, by Dr. Eastman and Dr. Arthur Giles, of "The History and Technique of the Vaginal Radical Operation." The points he further discussed were: (1) when is the anterior or the posterior incision to be chosen? when the combination of both? (2) which anterior section is better, the longitudinal or the transverse? (3) how is the uterus to be luxated? (4) shall and must the peritoneum be specially closed? and (5) shall the uterus after vaginal cœliotomy be fixed to the vagina or not? He could not advocate the extirpation of inflamed adnexa, unilateral or bilateral, by means of vaginal cœliotomy; even if the operation were

Digitized by Google

successful the majority of cases were not benefited. When performed for certain precise and clearly-defined indications vaginal cœliotomy gave excellent results but on account of its relatively small danger it had a tendency to be overdone.

Professor FEHLING (Halle) agreed with Dr. Cullingworth that they had to separate pelvic suppurations into those arising in the parametrium and pelvic peritoneum and those of the adnexa. In many cases of tubal suppuration the history and temperature gave no indication of the presence of pus, yet it was found on operation. As to the vaginal or abdominal route he agreed with Dr. Doyen that there was no fixed rule; every case must be dealt with on its merits. When the diagnosis was uncertain and when the disease was unilateral he preferred the abdominal route.

Dr. A. MARTIN (Berlin) said that, like Dr. Cullingworth, he laid great stress on the anamnesis, for in cases of gonorrhœa an expectant treatment was indicated, since in many instances such patients recovered without operation; but in septic cases operation was almost always required; and, indeed, these were the cases in which an operation might have to be performed even while an acute feverish condition was present. A difficulty often arose in the differentiation of these cases from extra-uterine gestation; often this was the condition found when gonococci or streptococci had been thought to be the cause of the illness. There was a cause of pelvic inflammation which had not obtained sufficient recognition, viz., the presence of the bacillus coli. This was responsible for many cases in quite young women; and the onset of menstruation not infrequently marked the commencement of the pelvic trouble, whilst a few years later definite swellings were found, and then, on operation, adhesions were generally present uniting the appendages to the intestines. In his earlier cases he sometimes regretted not having taken away the uterus as well as the appendages, but experience had taught him that in the long run those patients were generally the best off in whom the uterus was left.

Dr. MACAN (Dublin) thought that the two special points raised by Dr. Cullingworth had been rather lost sight of. The indications for operation depended almost entirely on accuracy of diagnosis, and this again on the knowledge of the bimanual examination. To carry this out properly the patient should be examined in the dorsal position, the right hand being used for the right side and the left hand for the left side. As to the time of operation, he would put this off as long as possible so as to get all possible advantage from the efforts of nature. He thought that when the vaginal route was employed for operation an estimation of the difficulties to be met with was much greater than by the abdominal method, since in the former the sense of touch had to be almost exclusively relied on.

Professor BYERS (Belfast) said that many points yet required to be cleared up. The greater one's experience the fewer no doubt were one's mistakes in diagnosis, but they all came across cases where it was impossible to determine before operation the *locale* of the pus. As to the method to be employed they had had the advantage of hearing the views of French and German experts; perhaps they in the British islands were apt to be too conservative in keeping to the abdominal route and there were cases better managed by a vaginal incision, as a palliative measure or as a means of tiding a very exhausted patient over a time until her strength was equal to an abdominal operation. What they wanted was more explicit information as to the indications for the respective methods.

Dr. HEYWOOD SMITH (London) related a case illustrating the two points on which Dr. Cullingworth had mainly dwelt. He thought the term "laparotomy" was philologically incorrect and scientifically misleading and ought to be replaced by the more correct term "cœliotomy."

Dr. WARD COUSINS (Portsmouth) observed that the various forms of pelvic inflammation ran so much into one another that a correct diagnosis of these complex disorders could seldom be made in the early stages, but all of them could be traced to some infective process. Many got well with very simple treatment, whilst in acute cases of suppuration the dangerous stage might often be relieved by simple incision and careful drainage. The position of the incision must be determined by the special features of each case. When distinct swellings were found and the organs were clearly diseased he thought the abdominal route was generally the best for dealing properly with them.

Dr. TAYLOR YOUNG (Sydney) agreed with Dr. Macan that British gynæcologists often handicapped themselves in making a diagnosis by adhering to the lateral method of examination. Removal of the uterus should be practised only in cases of bilateral suppuration and destruction of the adnexa. In the others simple incision might first be tried, as even if unsuccessful it would not interfere with future operation. But conservatism was not to be carried too far; a partially destroyed uterus was of no use after both the adnexa had been removed. The question to keep in mind was the patient's ultimate condition and from this point of view he thought the best results were obtained by the vaginal route.

Dr. LAPTHORNE SMITH (Montreal) endorsed the remarks of Dr. Cullingworth as to the immunity which the peritoneum acquired after one or more attacks of pelvic peritonitis. His experience was that these cases had a much smaller death-rate than those operated upon during a first attack. As to the route to be employed he had come to the conclusion that the abdominal plan was the best for all cases of large tumours of any kind, for pus tubes, hydrosalpinx, tubo-ovarian abscess, and tubal pregnancy; he would, on the contrary, employ the vaginal route for growths and collections situated low down in the pelvis. The advantages of the vaginal route were inestimable—no scar, no bugbear of hernia, and no buried sutures, while the mortality was almost *nil*. He was strongly in favour of removing the uterus when the tubes were full of pus and both ovaries had to be removed. This should usually be done through the abdomen and Trendelenburg's position was of great value.

Dr. AMAND ROUTH (London) agreed with Dr. Cullingworth that cases of perimetritis should not usually be dealt with during the acute stage, but this was not the case with puerperal septic parametritic abscess, which should be opened and drained through the vagina as soon as pus was suspected, and not be allowed to drift on till pus pointed above Poupart's ligament, as it only did in neglected or long standing cases.

Dr. HANDFIELD-JONES (London) agreed with Dr. Cullingworth that (1) large size of the pelvic tumour, and (2) recurrence of pelvic inflammation were the principal indications in deciding in favour of operation. In making a diagnosis it was most important to examine under full anæsthesia, since in cases of pus collections high up and situated posteriorly it was often impossible to map out the mass with certainty until the muscular parietes were fully relaxed. There could be no doubt as to the wisdom of waiting to operate until the acute symptoms had subsided. He failed to see the antagonism between the vaginal and abdominal methods: both were useful and suitable under different conditions.

Dr. AUST LAWRENCE (Bristol) remarked that when the vaginal swelling was most marked it was often wise to aspirate through the vagina, as some cases got well by this means even when no pus was found.

Dr. E. T. DAVIES (Liverpool) said that as to the route of operation the abdominal was generally the safer, as hæmorrhage and adhesions were more under control. Delay till the acute stage was often wise, but it was possible to delay too long, for if dense adhesions formed they made a subsequent operation much more difficult. The use of the aspirator as a means of diagnosis was a dangerous procedure and should never be employed unless immediately followed by operation.

After a few remarks by the PRESIDENT Dr. CULLINGWORTH replied.

Dr. F. J. MCCANN (London) read a paper on Clamp and Ligature in Vaginal Hysterectomy for Malignant Disease, which was discussed by Dr. HEYWOOD SMITH, Dr. E. T. DAVIES, and the PRESIDENT.

THURSDAY, JULY 28TH.

The second day's session was opened by a discussion on

The Use and Abuse of the Midwifery Forceps,

introduced by Dr. MILNE MURRAY (Edinburgh), who said that the selection of this subject arose out of the able address of Dr. Japp Sinclair at the Montreal meeting. He began by asking: "What is the special value of the forceps as a surgical instrument?" and his reply to this was that it enabled them to shorten the suffering and diminish the risk of childbirth. As to the indications for its use he considered that this was found whenever and only whenever they were assured that the danger of interference had become less than that of leaving the patient alone; this, of course, implied that the use of the forceps was in practically every case a matter of individual judgment and definite rules could not be laid down. A fœtal head and an ovarian

Digitized by Google

tumour could not be dealt with on the same lines. It was good practice to remove the latter as soon as it was detected, but the mere presence of a fœtal head in the pelvic cavity was not an adequate reason for its summary removal. It was on these grounds that a certain number of instances of improper use or abuse of forceps were due to errors of judgment; the instrument was employed when it should be left alone or else it was not used in cases where it was indicated. In addition, a large part of what might properly be called the abuse of forceps was due to faulty technique. He would sum up the matter thus: (*a*) the forceps were often used at the wrong times; (*b*) they were sometimes not used at the right times; and (*c*) they were often badly used at both times. The dangers of the forceps operation apart from the risk of septic infection (which was common to most operations) might be summarised thus:—1. The mother's parts might be bruised, lacerated, or otherwise injured by mechanical violence. 2. The too sudden emptying of the uterus might be followed by imperfect retraction and consequently dangerous hæmorrhage. 3. The fœtal head might be unduly compressed, lacerated, or otherwise damaged. He had met with an objection to the use of forceps due to the fact that there seemed to be a lingering doubt in the minds of some whether the abolition of the pain and suffering of labour would be an unmixed blessing. This seemed to be a survival of the same barbarous instinct which prompted the so-called religious objection to the use of chloroform in labour and was as unworthy of respect. For his part he had no such scruple and were he able to do so with safety he would gladly abolish every pain after the first and reduce the duration of labour to a bare minimum. As to the application of forceps at the wrong time, he wished specially to protest against their use before the os was dilated except under quite exceptional circumstances. Sometimes the fact that the os was not yet dilated properly was not recognised, owing to an examination being made in the absence of a pain, and if then the forceps were applied and a contraction came on the os might be found spasmodically contracted round the head and forceps, and if traction were persevered in disastrous results might follow. As an example of the harm which might result from not applying the forceps when they were required he mentioned an injury once common enough and now rarely seen—viz., vesico-vaginal fistula; but, short of this, an undue amount of maternal bruising and other damage might result from carrying to an extreme the reasonable reaction which had shown itself in many schools against the too frequent use of the forceps. In this connexion he mentioned the fact that in the Rotunda Hospital report for 1896-97 there was a record of 56 cases, in 45 of which the indication given was "delay in the second stage of over four hours." He thought it was a mistake that the element of time should be a primary determining factor. He saw nothing to be gained but much to be lost in waiting a minute after he was certain that progress was at an end, and the danger of interference was less than the danger of waiting. There was no wiser obstetric aphorism than the one: "Wait till you see what nature can effect, not what she can endure." If he were asked when he would apply forceps he would reply in the words of their distinguished President: "When the passages are in a fit state and nature fails to advance the head, then I should apply forceps." He directed attention to a class of case in which he thought the forceps might be used with greater discrimination than was commonly the case—viz., in occipito-posterior presentations of the vertex. His own view was that when flexion was deficient, as shown by the ease with which the bregma could be reached, the sooner the forceps was applied after the os was dilated the better. The forceps were sometimes abused by being badly used, and among these faults of technique he included the failure to use the most efficient instrument. The most efficient instrument was undoubtedly the one constructed on the principle first laid down by the late Professor Tarnier of axis traction. He thought a man who had used this would be as likely to revert to the old instrument as a man would be to give up a cycle of 1898 for a "bone-shaker" of the early seventies. To object to the axis-traction that it was complicated was an argument with which he had little patience. That a couple of rods and a handle-bar should present a serious difficulty to the acceptance of an immensely more efficient instrument was an argument scarcely worthy of a grown man; to hear it soberly raised as an objection made him wonder whether obstetrics had fallen into the hands of hemiplegics or general paralytics. He pointed out the advantage of the axis-traction forceps in procuring rotation and combated the view that it unduly compressed the fœtal head, while as to removing the forceps when the head had reached the perineum, he would as soon think of leaving the patient in the third stage of labour as of removing the forceps before complete delivery of the head. He maintained that by means of the forceps they were able to avoid laceration of the pelvic floor in cases where this would unavoidably occur if left to nature. As to the mode of applying the forceps to the child's head, he thought this should always be done so that the blades grasped the biparietal diameter of the head wherever situated. Extensive damage to the lower part of the vaginal canal, especially internal laceration of the perineum, was often caused by oblique position of the head or of the forceps at the outlet. The application of the forceps to the side of the head might require more care than the other methods, but they were there to take what care was necessary for the benefit of the patient. Lastly, to protect the perineum traction should be made in the intervals of the pains, under fairly deep anæsthesia, and using the left hand to control the uterine retraction. He never under any circumstances "supported the perineum."

Dr. W. S. PLAYFAIR (London) said that the day's discussion was the direct result of the address by the President of the Obstetrical Section at the Montreal meeting, and for his part he must take exception to the main thesis laid down by Professor Japp Sinclair that "gynæcology had become so largely developed as the direct result of surgical intervention in midwifery; the obstetrician provided material for the gynæcologist." Much of the development of gynæcology was due to abdominal surgery and this could have no relation at all to obstetrics. The bad results which were seen after the use of forceps were mainly due, not to the use of forceps *per se*, but to their faulty use. The forceps were rather to be regarded as a most beneficent instrument; it was the want of this which caused so much injury and loss of life in former times and it required the object lesson of the death of the Princess Charlotte to convince the profession that the prevailing practice was wrong. The forceps had obviated many cases of vesico-vaginal fistula—a complication hardly seen nowadays—and it had enormously lessened the use of the craniotomy forceps.

Dr. SMYLY (Dublin) observed that a point to be borne in mind was that whereas the forceps might at one stage be unsuccessful and the perforator might seem necessary, on waiting for time for a certain amount of moulding to occur it was sometimes possible to deliver easily by forceps. On the other hand, too long delay was inadvisable for this among other reasons, that if delay has been allowed till the patient's condition is grave delivery must be hastened. If it be done earlier proper care can be taken. Safety in the use of forceps lay in adhering as closely as possible to their employment under favourable circumstances—that is, where the head presented and had passed the brim by its greatest diameter, the os fully dilated or dilatable, and the membranes ruptured. When less favourable conditions were present the indications must be more definite, such as danger to mother or child, but under the conditions indicated they were often employed merely to save suffering.

Professor FEHLING (Halle) said he must confess that he was of those who preferred the old forceps, and he felt that they were often used too much; the tendency among students especially was to use the forceps in many cases where the proper treatment was to wait. He quite agreed with Dr. Milne Murray's rule that the forceps were to be used in those cases where the danger of using them was less than the danger of waiting. He believed much improvement would result from the teaching of the use of forceps by means of better phantoms than they possessed at present. He concluded by giving statistics of the use of forceps in his own clinic at Halle.

Sir WILLIAM PRIESTLEY (London) contended for a moderate and reasonable use of the forceps; he agreed with Dr. Smyly that in many cases waiting for a short time would allow the head to be moulded sufficiently for delivery to be accomplished either naturally or with ease by the forceps.

Professor STEPHENSON (Aberdeen) said that use and abuse must be taken together and the second term made to limit that intended to be included in the first. He could not accept the rule adopted by some that instrumental aid was to be used only when there were symptoms of danger to mother or child. It was the old cry: "Wait till nature begins to fail." The true principle was to aid whenever they

Digitized by Google

could without deranging the mechanism so as to avert symptoms of danger. But Dr. Milne Murray had fully vindicated the present frequent use of the forceps against the fallacies and strictures of those who would have them return to the custom of a hundred years ago.

Dr. MACAN (Dublin), referring to Dr. Milne Murray's direction that the forceps should be applied when the danger of delay was greater than the danger of delivery by the forceps, said that this seemed quite simple and at once gained assent. But when they tried to translate this into practice they found that it required great skill and experience to know when the danger of the operation was less than the danger of delay. He therefore always impressed on his students that the chief danger of delay lay in the want of antiseptics. Personally he considered that the greatest triumphs of the forceps were the cases which required least traction. If the force of resistance were the least greater than the driving force there could be no progress and here the slightest traction with the forceps would effect delivery. He could not agree that the forceps should not be applied till after the greatest diameter of the head had passed the brim, for it was when the head was fixed there that the indications for delivery were most urgent.

Dr. MUNRO KERR (Glasgow) said that it was the general teaching that the forceps should be applied without reference to the diameter of the child's head and he considered this to be very bad teaching because it involved a lack of exactness. If the head were high it was more difficult to grasp the head high, but it could be done with care; the more transversely the head was seized the better, especially in cases of contracted pelvis, because a slight departure from such a grasp readily resulted in injury to both mother and child.

Professor BYERS (Belfast) agreed with the dictum, "Wait until you can see what nature can effect; don't interfere until she fails"; but there were other cases in which no danger threatened and in which, other conditions being favourable, the use of the forceps was nevertheless justifiable. He was in accord with those who said that full dilatation of the os was necessary before using forceps; but an exception was to be made for certain cases of eclampsia and sometimes in the case of aged primiparæ. As to forceps at the brim, he preferred their use to turning in flat pelvis. When the head had been brought down to the perineum he preferred to complete delivery before removing the forceps.

Professor JAPP SINCLAIR (Manchester) expressed modified approval of the axis-traction forceps, but could not imagine a time when the ordinary long forceps would be discarded in favour of the axis-traction instrument. His address at Montreal had been misunderstood to some extent; he reiterated his statements that the use of the forceps was excessive and that the teaching of midwifery was inadequate. There was at least sufficient ground for reconsidering their positions.

Dr. ROBERT JARDINE (Glasgow) spoke of the use of the forceps in contracted pelvis. They had many cases in Glasgow and he believed that the forceps gave better results than turning. He had delivered 8½ lb. children alive through a true conjugate of 3 in. He wished to emphasise the danger of turning after axis-traction had failed; the result was not to save the child but sometimes to rupture the uterus. Craniotomy was then the proper procedure. Theoretically transverse grasp of the child's head was right, but practically it was often impossible.

Dr. HANDFIELD-JONES (London) thought it was unwise to teach students that the forceps must always be applied in the transverse diameter of the child's head; in attempting such an application it was often very difficult to lock the blades and much harm might be done by rough efforts in this direction. He was strongly in favour of axis-traction forceps and related cases to show their value.

Dr. SLOAN (Glasgow) observed that the old Sir James Simpson forceps were axis-traction forceps; the tractors were the man. In the so-called axis-traction forceps of modern days the tractors were there, but the man might not be. As to their use at the outlet of the pelvis, it seemed to him to pass the wit of man to know what service they could be there.

Dr. LAPTHORN SMITH (Montreal) said that nearly all day in his practice he was busy repairing injuries caused by the too early use of forceps or he was taking down the histories of women who had been injured by them. He saw tears of the cervix up to the internal os and tears of the perineum into the rectum caused by hurry on the medical attendant's part, perhaps because he had another case on hand or because some old gossip had remarked that some other patient was confined in two hours. His remarks applied to perfectly normal cases.

Dr. BRASSEY BRIERLEY (Manchester) said he was glad to hear Professor Sinclair apologise for the remarkable and misleading statements made at the Montreal meeting. He thought that the fault of the improper use of forceps was due to the way in which men learnt their midwifery; in Manchester they were mostly taught by old midwives. He maintained that practical midwifery should be taught efficiently by qualified men and women in hospital or district practice.

Dr. JOHN MOIR (Edinburgh) thought that the practice of the present day was not quite so successful as in the days when he was a student. He maintained that the secret of success was to keep a steady watch on the condition of the cervix, pushing it up when it seemed likely to become jammed down in front of the advancing head. If forceps were then required all danger of injury to the cervix was obviated. He earnestly advised that no interference should be resorted to as long as the case was progressing satisfactorily.

Mr. DRAPER (Huddersfield) endorsed the view expressed by Dr. Lapthorn Smith that it was very wrong to use the forceps merely to save the medical attendant's time; the delay allowable before applying the forceps in the second stage was not to be measured by hours but should depend on the condition of the patient. He also emphasised the importance of proper antiseptic precautions.

Dr. CONNEL (Peebles) confessed himself a convert to the axis-traction forceps; as a general practitioner, trained in the school of the elder Simpson, he could say that there was no comparison in the efficiency of the two instruments. The preservation of the perineum was among the not least important of their functions.

Dr. MORE MADDEN (Dublin) contributed to the discussion a short paper on the Use of the Midwifery Forceps and some Modifications in its Mechanism, after which Dr. MILNE MURRAY briefly replied.

Mrs. SCHARLIEB, M.D. (London), read a paper on a Case of Missed Labour which was verified by operation and by necropsy.

Dr. ROBERT JARDINE (Glasgow) contributed a paper on Aseptic Midwifery, with which the morning's session concluded.

STATE MEDICINE.

WEDNESDAY, JULY 27TH.

A discussion upon

The Pollution of Rivers and its Prevention

was opened by Dr. H. M'LEAN WILSON in the following words:—

There were, he said, five points which were offered for consideration—namely: (1) Who should administer the laws for the prevention of pollution of the rivers? (2) Are the present laws sufficient? (3) Is treatment of sewage on land to be required in all cases? (4) Should manufacturers' refuse be purified by the manufacturers themselves or by the sanitary authorities? (5) Should any standard of purity be adopted for effluents from sewage works or purified trade refuse? Probably all present agreed that the cause of the failure of the Rivers' Pollution Act of 1876 was the want of provision for proper administration. The sanitary authorities, to whom enforcement naturally belonged, were nearly all themselves offenders. The county councils created in 1888 in England and in 1889 in Scotland had the power of enforcing the Act committed to them. The county councils were naturally somewhat chary of dealing with pollution within the limits of county boroughs, and in Scotland other burghs within which the greater number of polluting manufacturing processes were usually carried on, and the county boroughs themselves have been chary of exercising their powers against individuals in their districts. The same Acts gave power, therefore, to the Local Government Board of England and to the Secretary for Scotland to constitute a joint committee representing all the administrative counties concerned in any river for the purpose of enforcing the Act of 1876. Such joint committees have been formed in three cases only—that of the

Digitized by Google

Ribble in Lancashire, where in 1891 a committee was formed representing the County Council of Lancaster and the four county boroughs of Blackburn, Burnley, Preston, and Wigan; that of the Mersey and Irwell, also in 1891, where the committee consists of members elected by the County Councils of Lancaster and Chester and the seven county boroughs of Manchester, Bolton, Bury, Oldham, Rochdale, Salford, and Stockport; and that of the West Riding in 1893, upon which were represented the County Council of the West Riding and the five county boroughs of Bradford, Halifax, Huddersfield, Leeds, and Sheffield. The foundation of the Water of Leith Commission in 1889 by special Act was on somewhat similar lines, but that body was armed with powers far in advance of those given to the joint committee. The formation of joint committees was a great advance, and may well be regarded as the key to the position. Some people advocate, with no little show of reason, that the preventive powers should be entrusted entirely to a central authority. 2. Are the present laws sufficient? The special rivers authorities have found the Act of 1876 faulty in many ways, and in 1892 the Mersey and Irwell Joint Committee, and in 1894 the West Riding Rivers Board applied to Parliament for further powers. In England there are two ancient bodies with special powers for dealing with river pollution—namely, the Thames and the Lee Conservancies, each armed with a special Act giving them powers very similar to the Lancashire and Yorkshire authority but having the additional power of carrying out actual works of conservancy and purification. The special Act of 1889 imposed upon the Water of Leith authorities the duty of carrying out the necessary purification works. Similar increased powers are being sought by the Middlesex County Council by a Bill now before Parliament. They ask to be empowered to improve the bed of a stream, to remove obstructions, to straighten the channel, to construct weirs, to regulate the discharge of compensating water, and to prevent the occurrence of any new pollution. A general Bill having a similar extension as its basis is also now before Parliament. From the foregoing it is clear that the Act of 1876 is generally found to be insufficient. The proposed Bill as it stands is weaker in some respects than either of the two special Acts on which it is founded. The points left undecided are the right of a manufacturer to discharge his trade refuse into a public sewer or of a sanitary authority to refuse to allow him so to discharge it, the prohibition of the sludging of mill dams, the power to remove obstructions to the stream, the absolute prohibition of any new pollution, and the proper supervision of the discharge of compensation water. It would be a great misfortune if the Bill were allowed to pass into law in its present state, as it would postpone indefinitely the solution of the whole question. 3. Is treatment of sewage on land required in all cases? It is not necessary to discuss this point where sewage is discharged into the sea or tidal waters, although even then solids should be removed. Land filtration is undoubtedly the best plan where sewage effluent has to be discharged into a stream—that is, where enough land of a suitable nature can be obtained for the purpose. Since the reports of the Rivers Commissioners unsuitable land is now less often laid out for sewage farms. The Massachusetts Board of Health plan of artificial treatment appears to offer a promise of satisfactory results. It is still uncertain, however, how any of these plans will affect trade pollution. Biological methods alone, it is generally admitted, can deal efficiently with sewage matter. While land is advisable, then, for sewage disposal, yet in special cases better results are likely to follow artificial filtration by biological methods. If a sufficiency of clean ground be secured round a surface well casing will be superfluous. The exceptional cases show the powerful effect soil-filtration has in removing impurities from water, so that villages which have from time immemorial obtained water from shallow wells have not actually gained a reputation for unhealthiness. 4. Should manufacturers' refuse be purified by the manufacturers themselves or by the sanitary authorities? In England the matter remains in doubt, but in Scotland it seems definitely settled by Section 110 of the Public Health Act of 1897. It is worthy of notice that the provisions of Section 116 do not include the preliminary treatment of trade refuse for the purpose of removing from it anything which would interfere with the treatment of combined sewage. Sections framed for that purpose have been inserted in a Wolverhampton Act of 1869, in a Bilston Act of 1896, and in a Bradford Act of 1897. It is not clear, however, and the fact that there are these private Acts of 1896 and 1897 renders it more doubtful, whether the proviso in Section 7 of the Rivers' Pollution Act enables an authority to compel a manufacturer to remove from his trade refuse any such injurious matters. 5. Should any standard of purity be adopted for effluents from sewage works or for purified trade refuse? If it were possible to have a fixed standard such as that recommended by the Royal Commission the labours of reformers would be easier. Such a standard would have to be regulated by chemical analysis alone. Throughout the discussion of these questions it must be borne in mind that the subject may be looked at from two different points of view. Sometimes the river to be purified is so offensive that the first aim of the reformer is to end the nuisance. Some rivers are used for drinking-supply and their purity requires to be jealously guarded, and in regard to others the question of fish becomes one of importance. Our object, however, in all cases must be to put a stop to the gross abuse of the rivers now so common and to bring them back as nearly as possible to their natural state.

Professor GLAISTER (Glasgow) desired to consider the question with regard to Scottish rivers. In 1896 from inquiries made among medical officers of health and other sources he dealt exhaustively with the subject before the Philosophical Society of Glasgow. In that address (copies of which were distributed) he showed that the result of twenty years' experience of the Rivers' Pollution Act was absolutely negative and that the state of the rivers was no better to-day—if not, indeed, worse—than in 1868, when the Commissioners made their inquiry. It could be said without fear of contradiction that practically every river in Scotland was polluted in a degree varying from a small addition of sewage up to every conceivable kind of trade and organic and inorganic filth. The machinery available against that state of things lay in the Rivers Pollution Act of 1876; in certain sections of the Public Health (Scotland) Act of last year; in certain clauses of the Gasworks Act, of the Salmon Fisheries (Scotland) Act, 1862, and at common law. The direct Act is probably the least useful on account of its cumbrous, costly, and inefficient nature. Differences of opinion exist with regard to the value of a legislative impurity standard. No doubt much difficulty surrounded the application of one set of standards for all rivers, but Professor Glaister would be glad to revert to the standard laid down before the Commissioners—namely, "Whenever water was so affected by a town or manufacture as to become unfit for supporting the life of fish and of green plants the pollution, from whatever cause, should be considered as an unsupportable nuisance to the riparian population." If any permanent improvement was to be effected in Scottish rivers it could only be done by amended legislation, and he would suggest a resolution from the Section to that effect calling for amendment of the Act of 1876 in the direction of the Lancashire and Yorkshire amended Acts of 1892 and 1894.

Dr. G. REID (Stafford County Council) said that with regard to joint boards he thought local conditions should largely determine their formation. There were numerous overlapping local authorities with different interests—the county boroughs, for instance, who as a rule were the great sinners, might be able to defeat the efforts of other bodies, such as county councils, by combination. He suggested county councils as the more suitable central authorities, except possibly in special cases. As to constructing works of sewage disposal he thought that it would not be wise to entrust anything but supervisory powers to county councils. He concurred with Dr. Wilson that it was impossible to fix any standard of purity of effluents in face of varying local conditions. In the case of populations on large streams it might be perfectly reasonable to admit a less highly purified effluent than in the case of small streams.

Dr. BRUCE LOW (Local Government Board) approved, in England at any rate, of the formation of joint committees to take charge of a watershed. He had known good paper schemes wrecked by the jealousy of interested counties. The assistance of Parliament appeared to be needed to substitute a certain amount of compulsion for permissiveness in the formation of joint rivers boards to protect rivers from pollution.

Dr. J. C. MCVAIL (Stirlingshire) observed that medical men were best fitted to inspect factories and rivers. A good deal of expense was involved in the purification of rivers, but the time had long since passed away when folk thought there

Digitized by Google

was no need for such a proceeding. The county councils wanted the district councils to take the matter up and the larger area seemed preferable. The smaller the local authority the more likely the introduction of undesirable influences. The election for school boards was entirely distinct from other things, why should it not be so in health matters? The central authority must keep a firm hand and compel, if necessary, the carrying out of the present Act, which he regarded as exceedingly weak. For instance, it was an offence against the Act to allow solid matter to flow into the river, but solid matter in suspension is not allowed at all. Now, unless solid matter is in suspension it cannot flow at all, so that the reading is absurd. He did not agree with Professor Glaister that the Act had done no good; in fact, it had achieved a good deal. By inspection and meeting with owners, without going to law, much had been done. Knowing that the matter is engaging constant attention causes much to be done. One manufacturer did a great deal to abate a nuisance while another did little or nothing.

Dr. HILL (Birmingham) observed generally that the subject of pollution of rivers was varied by such complicating conditions as volume and variety of polluting material and became one of great difficulty. In such a town as Birmingham it was hopeless for any sanitary authority to expect to cleanse the small stream which carried off the sewage of three-quarters of a million of people. Then there was the refuse of many factories, not only of Birmingham, but also of other towns higher up the stream. Birmingham got some £25,000 out of its sewage-farm while it spent about £35,000 or more. Precipitation and suitable land were both requisite for the treatment of mixed or complex sewage. In the Thames they had the sewage of many towns mixed with a large volume of water, and under exposure to light, aeration, and other conditions it apparently underwent a process of self-purification, for the sewage-polluted water of the Thames was drunk with apparent impunity by the Londoners. The presence of fish appeared to be no test as to the fitness of water for drinking, for some fish lived and fed round the mouths of sewers, while oyster-beds improperly placed had been known to spread typhoid fever. Large towns situated on small streams could never hope to keep such streams sufficiently pure for drinking purposes; they must necessarily go for their supply—like Liverpool, Manchester, and Birmingham—to a water-shed uncontaminated by a population.

Dr. BOND (Gloucester Combined District) said with regard to the new process of septic tank filtration the results are too convincing to leave much room for doubt as to the wide applicability of the system. At Exeter, in a small space of the size of that lecture-room, the sewage of 1500 persons was treated and left the tank a clear and bright-looking water. Far more could be done under common than under statute law. In the former the judge acted under the influence of equity rather than of mere law and was usually in favour of the plaintiff. Legal proceedings, however, were costly and attacked the interests of manufacturers. Private persons therefore fought shy of embarking upon costly litigation to control pollution of rivers. We wanted to give aggrieved persons the opportunity of acting through public bodies by a procedure analogous to that known in England as proceeding by "information" through the Attorney-General, as the matter was one in which the public was interested and should pay the cost. Harassing prosecutions could be avoided by making the consent of the Attorney-General a necessary qualification. He asked the opinion of the meeting as to the desirability of the following motion:—

That in view of the greater facilities for dealing with river pollution which are offered by action at common law than under existing statutes, it is desirable in the opinion of this Section that county councils and other river authorities should be empowered to proceed in this matter of common law whenever they may consider it desirable to do so, under such restrictions against undue exercise of this power as may appear advisable.

Sir HENRY LITTLEJOHN (Edinburgh) proposed the formation of a sub-committee to look into the matter and draw up a series of resolutions to lay before Friday's meeting and to include Dr. Bond's proposition among them.

Dr. HOPE (Liverpool) then read a paper upon

The Value of the Present Method of Estimating the Populations of the Great Towns in England.

The reasons for believing that the present estimate of the population of Liverpool is very much below what it actually is may be summarised in the following manner: (*a*) The natural increase of the population—namely, the increase in the number of births over deaths since the last census—exceeds 40,000; (*b*) the increase in the number of registered voters since the last census exceeds 26,000; (*c*) since the last census the number of inhabited houses in the city has been ascertained by special investigation to have increased by 14,448, and the number of houses which have been built in excess of those which have been demolished since the last census is close upon 2500. Each one of these considerations adds to the belief that the actual increase has been greater than the estimated increase. (*a*) sufficiently explains itself. With regard to (*b*) the number of inhabitants to a voter, taking the census average, is 6·9, but if only 6·5 be taken, and the increase in the number of voters be multiplied by this figure, it gives an addition to the population of 171,346, including the incorporated areas, which, added to the census population of the old city makes a total of 689,326. With regard to (*c*) the number of inhabitants to a house, taking the census estimate, is 5·6, and taking the occupied houses of the present extended city as a basis of estimate of the population it makes an addition of 80,908 since the last census and raises the total to 710,351. The mere addition of the births over deaths would raise the population to upwards of 670,000. These figures have reference to Liverpool as it now is, the estimate of the city being made as for one whole, but it will be remembered that an incorporation of Liverpool with its suburbs took place in 1895. If this incorporation had not taken place, and the city and suburbs had been dealt with by the Registrar-General separately, as would have been the case except for incorporation, the totals so obtained would have been greater by 23,000 than they are now. This shows one obvious fallacy of the method of estimation adopted. Assuming the underestimation of the population of the city to be about 50,000 the consequences, taken as a whole, are trifling. It merely causes relatively unimportant errors in the birth-rate and in the death-rate, making both of them too high; but the consequences in certain districts of the city of obvious errors in the estimate of the population are very grave. Vauxhall ward in Liverpool formerly was a notoriously unwholesome district, but for some years past great efforts have been made to ameliorate the conditions of the district, and yet, year by year, thanks to the gross errors in the population as estimated by the Registrar-General's method, the rate of mortality appears to be steadily going up. But erroneous estimates are no new thing: at the close of the last inter-censal period the Registrar-General's estimate of the population of the City of Liverpool showed an error of 100,000. With regard to London a quinquennial census is employed and the evidence that a quinquennial census is necessary is abundantly proved by the errors of estimate which arise even in five years, amounting in 1891 to no less than 241,000. Clearly what is wanted is a more frequent census for the whole country, certainly not less frequently than every five years. It is singular that the Registrar-General is satisfied, week after week and year after year, to publish, under the imprimatur of his office, figures which everyone conversant with the subject must hesitate to accept as correct. No doubt a quinquennial census would go far to correct these mistakes and tend not only to prevent the waste of time involved by the compilation and issue of fictitious returns, but also to put an end to the mischief which such returns give rise to. But, pending such a census, it is eminently unsatisfactory to find that the Registrar-General regards the subject as of so little importance as to decline to discuss it, preferring to leave the matter for his successor to deal with. Numerous tables were given to prove the various propositions advanced by the speaker.

Professor SALTET (Amsterdam) found the same difficulty attending the ten-year census in his own country. They had a register of changes of address which was not possessed in England. That register enabled them to make a more accurate estimate of the population.

Dr. SPOTTISWOODE CAMERON (Leeds) advocated the establishment of a quinquennial census which need not be of the same detail as that of the longer period. Sex and age statistics would be almost sufficient. Even an accurate estimate of the number of houses would effect much. A census should be taken in every place. Meanwhile, we should demand a quinquennial age and sex census throughout the country.

Dr. SYMONS (Bath) also drew attention to the necessity of having the details published for each district. The details were given of Plymouth Lighthouse population of 5 persons,

Digitized by Google

whereas details as to sex and age were not obtainable of 30,000 populations except by special application to the Registrar-General.

The PRESIDENT remarked that the time to obtain detailed particulars was while the returns were in the hands of the local authorities; a little outlay would then secure information regarding each alley and street.

PSYCHOLOGY.

WEDNESDAY, JULY 27TH.

After the Presidential address from Dr. CLOUSTON, which we published last week, a discussion was opened by Dr. JOHN SIBBALD, Senior Commissioner of Lunacy for Scotland, on

Suicide, its Social and Psychiatrical Aspects.

Dr. Sibbald's contribution to the debate was a paper dealing with the statistics of suicide as gleaned from the Government Bluebooks for England and Wales and for Scotland and he selected the figures bearing upon the alleged increase of suicide. According to the statistical returns the suicide rates per annum per million of population had risen during the past thirty years from 67 to 86 in England and from 40 to 54 in Scotland. The tendency to conceal the occurrence of death by suicide had diminished since insanity had become more recognised as a disease. He next referred to the statistics of the methods of suicide and considered that the most trustworthy were those of suicide by hanging; in the forms of death by firearms, drowning, &c., there was more difficulty in deciding whether the death was by suicide or by accident. In the cases of suicides by hanging the annual figures per million during the past 30 years were remarkably constant, being 25 for England and 16 for Scotland; they varied in particular localities in Scotland, but remained constant for each locality. In the forms of death by firearms, stabbing, cutting, poisoning, and drowning, in all of which it was more difficult than in the case of hanging to determine whether the death was by suicide or by accident, the total number of deaths in each form remained constant, but more of them were now attributed to suicide than to accident. For example, the total number of deaths by firearms was much the same to-day as 30 years ago, but more of them were registered as suicides and fewer of them as accidents; the rise in "suicides" was balanced by the fall in "accidents." Dr. Sibbald concluded that the increase in suicides by firearms, &c., was thus probably dependent on their mode of registration and was therefore apparent, not real. The constancy of the deaths by hanging, which were almost invariably suicidal, was a strong indication that suicides as a whole were not increasing as statistics apparently led one to believe.

Dr. A. HAIG (London) followed with a paper on the Causes of Suicide and limited his remarks entirely to

Suicide as the Result of Error in Diet.

His thesis was: mental depression and suicide are due to errors of circulation in the nerve centres, the errors of circulation are due to excessive uric acid in the system, the excessive uric acid is due to errors of diet. He referred to the daily, annual, and life fluctuations of uric acid, and maintained that the incidence of suicide tallied with the periods when uric acid was most abundant in the blood—namely, in the mornings, in spring and summer, and in childhood and in the full prime of life. Suicide was commoner in England than in Scotland because the English eat more meat and drink more beer, while the Scotch eat less meat and drink whisky instead of beer. Suicide increased with civilisation probably because of the more injurious diet. Suicide was commoner in men than in women probably because men were more exposed and ate more meat and because women excreted uric acid freely at each menstruation. Many drugs—e.g., cocaine—and tea and tobacco led to suicide because they interfered with the excretion of uric acid. Uric acid, in Dr. Haig's opinion, was thus the immediate cause of suicide and proceeded from errors in diet.

Professor MORSELLI (Genoa) had forwarded to the meeting a paper (in French) on

The Characteristics of Suicide by the Insane as compared with those of Suicide by the Sane.

The paper was translated and read to the members by Dr. JOHN MACPHERSON, one of the honorary secretaries. The characteristics of suicides by the insane were the painful methods used, the reiteration of the attempts, their sudden and impulsive nature, and the existence of heredity and precocity.

Dr. BLANDFORD (London) opened the discussion. He did not accept *in toto* Dr. Sibbald's explanation of the statistics of suicide and doubted that the reluctance to acknowledge suicide as a cause of death was diminishing. Contrarily to Dr. Haig he thought that if all attempts at suicide were registered as well as the actual suicides it would be found that women were as often suicidal as men.

Professor BENEDIKT (Vienna) was of opinion that many suicides might be prevented were we able to at once place under care and control members of the public as soon as they were recognised to be suicidal. He thought that misery and privation had not been sufficiently referred to as causes of suicide and he referred to suicide amongst women before marriage and during pregnancy.

Dr. YELLOWLEES (Glasgow) thought that misery as a cause of suicide was increasing.

Dr. MACDONALD (New York) said that in his country the recent legislation for the punishment of persons who attempted suicide had—through the agency of the press, which took a delight in recounting the details of the methods attempted—given an impetus to suicide.

Dr. URQUHART (Perth) said that he had tried the dietetic regimen suggested by Dr. Haig for melancholia but without success.

Dr. JOHN MACPHERSON (Stirling) considered that the uric acid diathesis was not so much a cause of insanity as a sign of degeneracy. Suicide was due either to a blind impulse to die, as in the degenerate, or to a conscious desire to escape pain.

Dr. MERCIER (London) was of opinion that suicide was due to an exaggeration and perversion of the instincts of reproduction and duty.

Dr. NICOLSON, Lord Chancellor's Visitor in Lunacy, thought that suicide was a question of the balance of motives in relation to one's environment or supposed environment.

Mr. HAYES NEWINGTON (Ticehurst) referred to suicide in children from spite or ill-temper.

Dr. J. F. SUTHERLAND, Deputy Commissioner in Lunacy for Scotland, thought that the misery of the people was not increasing and that possibly this was the reason why suicide was not increasing. He agreed with Dr. Haig's views and suggested that the greater number of suicides in England as compared with Scotland might be due to the institution of the coroner's inquest.

Dr. SIBBALD, in his reply, said in the case of a topic of discussion such as suicide general statistics were of much more value than individual experience.

Dr. HAIG, in his reply, said that degeneracy of the race, if it existed, was due to errors of diet.

Dr. J. F. SUTHERLAND read a paper on

The Insanities of Inebriety from the Legislative and Medico-Legal Standpoints,

in which he mentioned several clauses which it was very essential should be added to the Bill at present before the country in order that it should deal with the inebriate effectively.

Dr. G. R. WILSON thought that this meeting was a good opportunity to bring pressure upon the authorities. It was agreed that a recommendation be made to the Council to bring the desirable clauses before the authorities.

Dr. IRELAND, Dr. TEMPLEMAN, and Dr. YELLOWLEES also spoke.

Mr. C. A. BOIS and Dr. N. T. KERR of Hartwood Asylum contributed a paper on

Clinical Studies with Spleen and Thyroid Extract,

in which they described the actions which they had observed to occur in patients taking splenic extract—e.g., an increase in weight, some degree of poikilocytosis, diuresis, an increased action of the bowels, and sometimes mental excitement. Therapeutically splenic extract was most beneficial in adolescents, especially in stupor cases. It aids the action of thyroid and is most effectual in the form of capsules of liquid extract given half an hour before meals.

Dr. C. C. EASTERBROOK (Morningside Asylum) read a paper on

The Action of Thyroid and Parathyroid Extracts upon Metabolism in the Insane.

He first referred to the conflicting results of the removal of the thyroids and parathyroids and to the very diverse

Digitized by Google

views which had arisen therefrom. The idea occurred to him that light might be gained from the pharmacological side by the administration of parathyroid extracts which had never previously been exhibited in the human subject. The patients were kept at rest in bed and upon a fixed mixed diet in order to control metabolism. The external parathyroids of the ox were employed. They were at first administered by the mouth, both in the fresh form and after being dried in a sulphuric acid chamber, but in both cases with negative results. They were next given in the form of hypodermic injections of extracts in glycerine, in sulphuric ether, and in 10 per cent. sodium chloride solution, and in relatively enormous doses. No actions comparable to those of thyroid were produced, and the only effect observable was a slight rise in pulse-tension similar to that which follows the injection of many other organic extracts. Dr. Easterbrook next made some observations on the action of thyroid based upon an experience of nearly 100 cases of treatment amongst the insane. In nearly all the cases the drug was given in doses sufficient to produce thyroidism, and the phenomena observed proved indubitably that thyroid is a profound katabolic stimulant. With the patient at rest in bed and on a fixed mixed diet, there is a great increase in all the excreta, especially in the water and carbonic acid and to a less extent in the urea and other products of nitrogenous metabolism. Thyroid thus greatly accelerates the splitting up and oxidation of the tissues, the fats suffering most severely, the carbohydrates next, and the proteids least. The anabolic reaction which sets in after thyroid treatment is explainable on Hering's theory of the internal self-adjustment of bioplasm. The changes in the blood during thyroidism probably indicate that the drug is conveyed by the blood to the tissues, but the early prominence of nervous symptoms during large doses of thyroid, the signs of central nervous hyperactivity followed by those of exhaustion, and the early increase of the phosphoric acid in the urine (which is probably derived from the excessive oxidation of the "phosphorised constituents" or "azotised fats" of the grey matter) indicate that thyroid specifically stimulates the central nervous system and through it the metabolism of the tissues. Dr. Easterbrook finally drew attention to the similarity between the "tetanic" symptoms of parathyroidectomy, the acute "neurotic" symptoms of thyroidectomy, and the toxic phenomena of thyroidism. He suggested that the essential result of thyroidectomy was an artificial myxœdema and that the acute or "neurotic" effects of thyroidectomy were accidental and, like the symptoms of parathyroidectomy, might be accounted for (1) by the youth of the animal operated upon; (2) by the interference with the very full nervous connexions of the thyroid; and (3) by the wounding of the thyroid, in consequence of which the spilt colloid is more rapidly absorbed and so gives rise to symptoms of thyroidism.

THURSDAY, JULY 28TH.

Mr. WALTER BERNARD (Londonderry) read a paper on

Defective Children and the Early Training of the Mentally Afflicted.

He commenced by saying that in 1888 Conolly urged that the early recognition of the mentally abnormal in the child should give the impetus to remedial treatment. He (Mr. Bernard) had only studied the subject as an ordinary practitioner, but he was sure that much might be done if they only began early enough. He would not trespass on the time of the meeting, but submit his views in a few general propositions: (1) is not the first manifestation by an infant of mental deficiency capable of being met by such methods of correction, suggestion, and appeals to imitativeness that the pathological in the child may gradually be guided to the physiological? may not the adoption of domestic treatment begun early prove ameliorative and abidingly effective? (2) the special treatment of the separate faculties has not received enough attention from medical men; (3) medical councils and examining bodies ought to insist upon practitioners being educated in the earlier recognition of abnormal mental states in the child; (4) it is most necessary to remember that early mental sanitation has a most important effect upon the recurrence of insanity; and (5) the Association should devote itself to a thorough examination of this subject. A table should be drawn up somewhat as follows: (1) rules for guidance before dentition; (2) rules during and immediately after this season; and (3) rules up to the third and fourth years; ages after this will be found in books on mental diseases. Departures from the normal may be recognised very early by the way in which the child laughs or cries or sucks. The process of growth, muscular, physical, or mental, must be observed. Is there normal progress in all these? If not, is any one overshadowed by the others?

Dr. SHUTTLEWORTH (Richmond, Surrey), who apologised for his absence during the reading of most of Mr. Bernard's paper, was happy to say that the education of defective children was spreading far and wide. He himself held office under the London School Board on purpose to look after this very subject. The children were taught in special classes and so had more individual attention than was possible in other classes.

Dr. FLETCHER BEACH (London) followed. He quite agreed with the necessity for early diagnosis. He wished to draw attention to the good work done by the National Association for the Protection of the Feeble-minded. This body provided for the care of children, especially girls, born of feeble-minded parents, and so minimised the chances of the same type being illegitimately produced in a future generation. Children were taken in as early as four years old. The subject was a most important one, and he was glad to say it was every day receiving more attention.

Other papers followed, notably one by Dr. W. R. DAWSON (Finglas, Dublin) and Dr. D. F. RAMBAUT (Grangegorman, Dublin) upon the Ocular Phenomena in General Paralysis, which we hope to publish in a future issue.

FRIDAY, JULY 29TH.

Hypnotism, its Phenomena and Theories.

Dr. CLOUSTON opened a discussion upon this subject. In his introductory remarks he said that he thought they had better consider the subject from the following points of view: (1) the phenomena of hypnotism and their explanation both from a physiological and a psychological view; (2) the employment of hypnotism in medical practice; and (3) its uncertainties and dangers—did it leave any residuum in the brain? why are only certain people hypnotisable? He would only say further that the two gentlemen who were to introduce the discussion were Dr. Milne Bramwell, a physician and a practical hypnotist, and Mr. F. W. H. Myers of Cambridge, one of the most learned psychologists in the kingdom. He now called upon Dr Milne Bramwell to read his paper.

Dr. MILNE BRAMWELL (London) said that hypnotic theories were very conflicting and it was impossible to eliminate the personal element from the equation. He had been led to take up hypnotism owing to the case of a personal friend and patient of his own who suffered from traumatic perineal fistula. He was in a very miserable state owing to his having constantly to empty his bladder and though no stricture existed he fancied he could not pass a catheter. Dr. Bramwell in trying to think of some remedy short of a surgical operation remembered the work of Braid and determined to try hypnotism. He therefore hypnotised his patient for three days and then, when in the hypnotic trance, made curative suggestions, such as that there was no need to micturate every 15 minutes, that the catheter could easily be passed, and that the patient should sleep. All these suggestions were acted upon when the patient was in his normal state. The fistula soon closed and the man recovered his health and spirits. Another remarkable case was that of a woman suffering from pruritus vulvæ and eczema in addition to some uterine retroflexion. He attempted to hypnotise her at her own request after she had been treated in every possible way. He failed altogether sixty-seven times. The sixty-eighth time he succeeded in hypnotising her and made suggestions that the pruritus should cease, that she should sleep and generally be well. All these things came to pass and the eczema very soon disappeared. This was three years ago and she had never had a relapse. Dr. Bramwell related other medical cases, notably one in a very neurotic girl with ciliary spasm who, after hypnotism, became strong, well, and happy. The ciliary spasm persisted for some time but eventually ceased. Passing to the surgical side of the question, Dr. Bramwell gave a *résumé* of his trials of hypnotism for surgical operations at Leeds. (An account of them appeared in THE LANCET of April 5th, 1890, p. 771.) In Dr. Bramwell's opinion the patient is not at the mercy of the operator; as for possibility of criminal suggestion, he had found patients to refuse suggestions—e.g.,

Digitized by Google

putting arsenic in tea—which they would refuse in a normal state. He had never seen any bad results or residua, or the formation of an hypnotic habit.

Mr. F. W. H. MYERS (Cambridge) then delivered a most interesting speech upon The Psychological Side of Hypnotism. He began by thanking the officers of the British Medical Association for permitting a layman to intervene in their debates. He understood that what was desired was some attempt at a coherent psychological presentation of the multifarious and perplexing facts now commonly grouped under the name of hypnotism, which facts physiology was not as yet able to explain. If a somewhat closer approach could be made on the psychological side this must needs be by bringing into comparison a great mass of cognate life-phenomena, such as hysteria, ordinary sleep, and somnambulism. The analogies and differences between hypnotism and hysteria were particularly instructive. Both in hypnosis and hysteria there were disaggregations of the personality, at first apparently similar, afterwards seen to be governed by quite different laws. To understand what happened in either case it was convenient to picture to oneself human personality as in a certain sense stratified, part of it lying above and part of it below the threshold of consciousness, the level above which thought or sensation must rise in order that it may enter into our waking life, or become subject to our voluntary control, or find a place in our chain of memories. Now, the characteristic trouble of hysteria was that fragments of faculty, of power, of sensation or motion, which it was desirable to retain *above* the conscious threshold, were apt to sink down *below* that threshold and thus to become useless to the hysterical patient. For instance, the patient would suffer from hysterical paralysis, say, of one leg or from a diminution of her field of vision while yet there was no perceptible organic injury to brain or leg or eye. What was thus lost could not be recovered at will, but might nevertheless be suddenly restored for a time or permanently by some shock, as when an hysterical paralytic patient recovered the use of her limbs in the terror of a fire, or was able to discern a terrifying object such as a stuffed mouse when it was brought into that part of her normal field of vision of the use of which hysteria had deprived her. With the hypnotised subjects, on the other hand, the case was quite different. They were able to recall at will from beneath the threshold any faculty or sensation which they might have lost through hysteria, so that in just the ways in which hysteria could destroy, hypnotism could fulfil, and they were able also to send down beneath the threshold and dismiss from consciousness sensations which they wished to get rid of, even such insistent sensations as the pain of an operation or of childbirth. The next point of great psychological importance was the analogy between hypnotism and sleep. The essential fact of sleep was the shutting-off of the supraliminal life—the life concerned with facts above the conscious threshold and the consequent increase of inward subliminal recuperative power. Hypnotism in the first place made our entry into this regenerative phase of our personality easy and certain. It did more than this, for in hynotic trance the subliminal plasticity was more marked than in ordinary sleep and the subliminal control intenser, so that hypnosis sometimes seemed to be to sleep what sleep was to waking. Indeed the leading facts of hypnotism, both for physician and for psychologist, the facts which called most pressingly both for explanation and for development, were those profound sanative regenerations which had now so often transformed the dipsomaniac and the morphinomaniac into self-controlled and useful members of society. But how, after all, was this further control over subliminal plasticity—over the *vis medicatrix naturæ*—actually reached? The consensus of hypnotists now declared that the secret lay in suggestion. But what was suggestion? Did the hypnotiser infuse power or merely evoke it? The speaker believed that in some cases there was actually a transmission of power, of some subliminal power akin to what he had termed "telepathy." But in many cases there was manifestly no such transmission: the hynoptiser merely taught the subject to start self-suggestions of his own. What it was that made those self-suggestions effective, that helped him to take hold, no theory could at present tell us. We might learn something by observing prevalent forms of self-suggestion outside the doctor's consulting-room altogether. One of these popular self-suggestions was the fountain of Lourdes, another was so-called Christian science or Mind-cure. Both of these took advantage of deep-rooted beliefs, although expressed with a superstition or an extravagance repulsive to the scientific man. It was, however, the duty of science to clarify, to utilise, to interpret whatever of real self-suggestive efficacy might lurk in any superstition, in any extravagance. By some means or other—and only wide experiment could show what means were best—science must subject to her own deliberate purposes that intelligent vital control, that reserve of energy, which lay beneath the conscious threshold and worked obscurely for the evolution of man.

Dr. YELLOWLEES (Gartnavel, Glasgow) considered that the hypnotic power did not so much lie in the operator but that it was a question of special receptivity in the subject. He found that he could not always succeed even when both he wished to hypnotise and the subject was willing to be hypnotised. As to the question of crime, Dr. Bramwell had cited the instance of putting arsenic in tea, but supposing it had been a matter of merely signing a document would not the subject have agreed to that?

Professor BENEDIKT (Vienna) said that he was quite certain that hypnotism did enfeeble the will. He maintained that if you make an instrument of a man he became attached to you—in fact, haunted you. Professor Benedikt then related a case illustrative of this.

Dr. ROBERTSON (Murthly) detailed his visit to Nancy at the instance of a Commission of the British Medical Association. Luy's results had been discredited and the Commission reported that they must be received with caution. He had seen wonderful results in relief of pain in sciatica and the like in Bernheim's clinic and cited some examples from his own practice where he had used hypnotism with great success in lieu of hypnotic drugs.

Dr. DERCUM (Philadelphia) followed. He quite agreed that hypnotism had its dangers and related the case of a girl in whom he had cured an hysterical joint by hypnotic suggestion. She, however, regularly haunted him afterwards and he had to transfer her to a hydrotherapeutic establishment, having previously suggested to her that this form of therapy was the one for her condition.

Other speakers followed and the debate terminated.

NEUROLOGY.

WEDNESDAY, JULY 27TH.

Dr. FERRIER (London) opened a discussion on

The Treatment, Curative and Palliative, of Intracranial Tumours.

He remarked that the problem of the treatment of intracranial tumours was one of very great interest and one which showed remarkable divergence in the opinion of those who had specially studied the problems involved in it. The percentage of operable cases, if one took into account the extreme views, varied between 2 per cent. and 15 per cent. His opinion was that only 7 per cent. were capable of being dealt with surgically. There were difficulties attending the operation and cases had to be looked at from two points of view—(1) in reference to recovery; and (2) in reference to relief from the symptoms which were present before operation. In 55 cases of which he had particulars operated on between January, 1896, and the present date, 20 died after a few days (37 per cent.); 16—i.e., 29 per cent.—died within a year; 12—i.e., 22 per cent.—passed out of the surgeon's hands; and 7 were alive a year after operation—i.e., 13 per cent. of what may be regarded as complete recovery. Further, of 38 cases treated surgically at the National Hospital for the Paralysed and Epileptic 15 per cent. died in a few hours, 35 per cent. died after some weeks, in 20 per cent. the result was uncertain, and in 6 cases life was prolonged over a year or more. On the whole, cerebral surgery was beneficial in its results. The immediate mortality was not greater than in other severe operations, and the mortality could be appreciably diminished by operating, as Mr. Horsley had recently recommended, in two stages, thus lessening the effects of shock, which were apt to be severe. Most tumours, however, were infiltrating and therefore not easily to be extirpated, and on this account there was a greater tendency to recurrence than after the removal of tumours elsewhere; and it was most desirable, if possible, to find some way of checking the growth of the tumour. Another difficulty which had to be faced was that of deciding whether the tumour was cortical or subcortical. Yet in such doubtful cases exploratory

Digitized by Google

operation was not only justifiable but desirable, for it was found that even trephining relieves the symptoms of cerebral tumour, and more especially has an influence on the optic neuritis. One question of great importance arose in reference to those cases—viz., should trephining be done in indefinite cases or even in cases in which it was known or suspected beforehand that the growth was not capable of being completely removed? The decision of this difficult question must, he thought, depend upon the particular case and it was perhaps better to put the responsibility of deciding upon the patient after explaining to him and his friends all the risks of the proceeding. In reference to cerebellar tumours, which were regarded by some as indefinite in their symptoms and undefinable in their position, he was of opinion that the risks of operation had been somewhat exaggerated, for experiments show that extensive interference experimentally with the cerebellum was not attended with any fatal effect. On the whole it could be shown that operative interference was followed in a certain number of cases by what might be regarded as complete recovery—i.e., immunity from symptoms for at least a year after operation—and in another class of cases by much relief to all the serious symptoms even if permanent cure did not ensue. Operation was probably to be recommended in a large number of cases. The relief of symptoms by medicinal measures must also be kept in mind and it was now recognised that iodide of potassium and mercury often relieved the symptoms and presumably influenced the growth of tumours which were non-specific and might be even malignant.

Dr. DERCUM (Philadelphia) agreed with Dr. Ferrier in his statement that tumours other than syphilitic, especially gliomata, were, as had been some years ago pointed out by Seguin, very manifestly influenced as regards their symptoms by anti-syphilitic treatment. In reference to the possibility of influencing the growth of brain tumours he related a recent unsuccessful attempt of his own to influence by means of tuberculin the symptoms apparently arising from a tumour of the brain associated with otorrhœa of many years' standing. A large tuberculous mass was afterwards found present in the brain, apparently due to infection from the middle ear and erosion of the temporal bone. He quite agreed with Dr. Ferrier's views as to the great relief afforded in many cases of indefinite or non-localisable tumour by simply trephining the skull.

Dr. COLLINS (New York) expressed surprise and gratification at the large percentage of cases in which not only relief but actual recovery had followed in Dr. Ferrier's cases and associated these results with the matchless surgical skill of Mr. Horsley. He was in the heartiest accord with Dr. Ferrier as to the relief afforded by operation and as to the accessibility to operation of some cerebellar tumours. He strongly advocated lumbar puncture, even carried out daily, for the purpose of relieving optic neuritis (choked discs), and he thought that the use of toxins such as Coley's fluid, &c., in cases of intracranial tumour offered prospects of relief which were by no means small. But many tumours must remain, for some time at least, unlocalisable. These, he thought, should be operated upon—i.e., trephining should be carried out in the hope of obtaining at least relief, perhaps even arrest of the symptoms. And although every syphilitic case should be energetically treated with mercury and iodide of potassium delay in operating in any case in which this treatment was ineffective or inadmissable was almost criminal.

Sir WILLIAM BROADBENT (London) remarked that his experience was small and not very favourable of operation in cases of intracranial growth, but he was of course delighted to have the more sanguine view of Dr. Ferrier, and looking back on the early difficulties which he could remember associated with ovarian operations, &c., he was not inclined to despair of cerebral surgery. His experience was that in cases of intracranial tumour the neuritis was greater on the side opposite the tumour. As regards the effect of iodide of potassium he had many years ago treated a patient in whom there was a negative history of syphilis and who had all the symptoms of cerebral tumour with iodide of potassium, relieving all his symptoms. Quite recently he had again seen him with a recurrence of his symptoms and he mentioned this as a case of intracranial tumour, almost certainly non-syphilitic, in which anti-syphilitic treatment had relieved the symptoms.

Dr. JOHN M. MACCORMAC (Belfast) said he was inclined to be optimistic, although results now only indicated hope in the future. He found phenacetin useful for the headache and hyoscin for the vomiting of cerebral tumour.

Dr. BEEVOR (London) mentioned four cases upon which he had operated which were now alive after two years or more. He was in favour of operation for palliation of the symptoms in cases of non-localisable or non-removable tumours. In such cases if no relief followed trephining he would advise puncture of the ventricles.

Mr. WATERHOUSE (London) had trephined in ten cases, four of them cases of infiltrating growth. In three of these all symptoms—headache, vomiting, &c.—disappeared at once; in the other case occasional headache persisted, but was easily relieved. Optic neuritis also disappeared in these cases, so that much relief was afforded.

Dr. E. F. TREVELYAN (Leeds) doubted whether tuberculous tumours so frequently became obsolescent as was supposed and in his experience such tumours were usually multiple.

Dr. MICHELL CLARK (Bristol) thought that hardened gummata not removed by anti-syphilitic treatment were usually found in cases in which the anti-syphilitic treatment had not been adopted in the early stage and he called attention to a class of case of cerebral tumour in which spontaneous recovery occurs.

Mr. J. PAUL BUSH (Bristol) spoke of the difficulty of the surgeon had in deciding at an operation whether he had to deal at the margin of a growth with healthy brain tissue or morbid growth.

Mr. COTTERILL (Edinburgh) thought that in spite of success operative treatment of cerebral tumours was not satisfactory. Yet exploration and removal of pressure seemed important and desirable and he detailed various important points as to the technique of operation.

The PRESIDENT cordially endorsed Dr. Ferrier's view and gave details of his own cases. Out of 123 of his cases however, examined post mortem only 5 could have been successfully treated by removal of the tumour. He referred to the spontaneous subsidence of symptoms in certain cases and expressed the view that such cases were possibly not cases of tumour but of hydrocephalus associated probably with meningitis. He expressed surprise at the favourable results furnished by Dr. Ferrier's cases and attributed them to the careful consideration of cases, by which certain cases were not submitted to operation, and to the care and skill with which the operations were conducted. He had not been so much impressed as some speakers apparently were with the palliative results of operation.

Dr. FERRIER, in reply, said that in his experience optic neuritis as a result of frontal tumour most often occurred on the same side as the growth, and he hesitated to express a definite opinion on the efficacy of lumbar puncture. His views, of course, as to "recovery" were necessarily modified by the fact that he regarded cases living a year after operation as cases of recovery, and also he regarded cases as recovered even if paralysis remained—paralysis the result of destruction caused by the growth before the operation had been undertaken.

THURSDAY, JULY 28TH.

Dr. BUZZARD (London) opened a discussion on

The Influence of Micro-organisms and Toxins on the Production of Disease of the Cerebral and Peripheral Nervous System.

He began by stating that he could not expect to do more with such a subject to discuss than throw out fragmentary suggestions which might be useful to other workers at this highly interesting aspect of neurology. Micro-organisms probably acted in two different ways—directly by the actual effect of the organisms themselves on the nervous tissues and indirectly through the agency of chemical substances produced by the action of the micro-organisms on the blood or other tissues of the body. Diphtheritic paralysis was probably the most striking and undoubted condition showing the effect of a chemical substance probably resulting from the action of the bacilli. The ordinary acute anterior poliomyelitis had always seemed to him to be a disease of infective character, and the fact that as a rule cases occurred sporadically did not seem to him to militate against such a view. Basic meningitis had lately been distinctly shown by Still to be microbic in origin, yet all the cases in the Hospital for Sick Children during the last ten years had been sporadic cases. So the fact that infantile paralysis usually occurred in isolated cases was evidently no argument against its bacterial origin. Further, it was not uncommon to find that in a family in which a case of infantile paralysis occurred one or more of the other children were ill with

Digitized by Google

similar symptoms, their illness, however, not resulting in paralysis. He also referred to epidemics of the disease which had been described by several observers. The poison usually falls with greatest force on the anterior nerve cells, but is not always confined to them, for convulsions occasionally occur, pains in the limbs are not infrequent, and spasticity may result. He then referred to another disease—insular sclerosis—and said the view enunciated by Pierre Marie was apparently gaining ground—viz., that this disease is really an infectious one. Patches of myelitis undoubtedly do occur as a sequel to infective fevers. But while not claiming that this was the same condition he thought that the periods of remission in disseminated sclerosis, so similar to those occurring in constitutional syphilis, indicated the infective character of the disease. Tabes was another disease the close connexion of which with syphilis no one could doubt. It was an interesting question how far tabes was a result of specific infection and he suggested that not syphilis merely but also chancroids might be the infection preceding tabes. We know that neuritis may follow different kinds of microbic infection and probably myelitis also may do the same. There seems no reason why tabes should not similarly follow different kinds of microbic infection.

Dr. DERCUM (Philadelphia), after thanking Dr. Buzzard for his suggestive address, remarked that the action of toxins was probably a general one on all the tissues, with a local expression at some very susceptible part.

Dr. JOSEPH COLLINS (New York) had found in the examination of cases from the Vermont epidemic that the nervous system generally was affected, yet no specific organism was found. He did not agree with the view that disseminated sclerosis is infective. He thought a more probable explanation was that it was a result of congenital abnormalities. The nutritional balance of the cells of the nervous system was also of much importance in reference to nervous disease.

Dr. F. J. SMITH (London) related two cases of apparently some infective nervous affection after a septic wound and suggested that in such cases where the symptoms pointed to peripheral rather than central affection the transference of symptoms from one side to the other should be regarded as the result of nerve influence.

Dr. JOHN M. MACCORMAC (Belfast) remarked on the great divergence of opinion as to the connexion between tabes and syphilis and expressed the opinion that the changes in the nervous system in disease are chemico-physical in nature.

Dr. J. A. ORMEROD (London) thought that in tabes there must be more than mere microbic infection, probably personal susceptibility. For it is well known that tabes occurs ever so much more frequently in men than in women and cases of Friedreich's ataxy became much worse after an illness. Indeed, in some cases the illness seems to evoke the first symptoms and he would be inclined to think the microbic origin of disseminated sclerosis and even of infantile paralysis was "not proven."

Dr. R. A. FLEMING (Edinburgh) thought that in peripheral neuritis the vaso-motor nerves probably suffer and so there is exudation into the sheaths with pain and paralysis.

Dr. MOTT (London), in detailing the changes which he had found in two cases of beri-beri, remarked on the direct effect apparently exerted on the cardiac muscles by the poison of this disease and on the severity of the clinical symptoms as compared with the amount of change found in the nervous system.

Dr. FERRIER (London) remarked on the great suggestiveness of Dr. Buzzard's address, but was inclined to regard the infective theory of the origin of disseminated sclerosis as seductive but not proven. Of the close connexion between syphilis and tabes dorsalis and also general paralysis of the insane he had no doubt.

Dr. ALEXANDER BRUCE (Edinburgh) had found in a case he had examined recently, in fresh foci of disseminated sclerosis, a blood-vessel in the centre and he thought that the change probably spread from this vessel and was caused by some toxic substance which had the effect of dissolving the myelin. The change occurred symmetrically round the vessel and evidently spread from it.

Dr. E. F. TREVELYAN (Leeds) described a condition of disseminated myelitis found by him in dogs which died after canine chorea and distemper and he described a case in which death occurred eighteen days after exposure to cold. There was suppuration in the back muscles, empyema, and myelitis.

The PRESIDENT thought that toxins in many instances gave rise to changes, but he thought that toxins were not always of microbic origin but were produced sometimes inside the body. He referred to the fact that second attacks of infantile paralysis were practically unknown as evidence of infective character. He thought herpes zoster was probably microbic and facial paralysis seasonal. He referred to muscular atrophy (myopathy) with little change in the nervous system as occurring as a sequel to sprue and he was inclined to regard disseminated sclerosis as a result of intoxication.

Dr. BUZZARD replied on various points raised, and the PRESIDENT, in conclusion, thanked him for his introductory address.

Dr. BEEVOR (London) read a paper on

The Action of the Latissimus Dorsi in Hemiplegia.

He said that this muscle had three different actions—in moving the arm, in coughing voluntarily, and in coughing reflexly. In hemiplegia the voluntary action in moving the arm was usually lost on the paralysed side, the voluntary action and the reflex action in coughing both usually remaining. Sometimes, however, the voluntary action in coughing was also lost but the reflex action remained. He remarked on the possible usefulness of the condition as a diagnostic sign.

PATHOLOGY.

WEDNESDAY, JULY 27TH.

Dr. G. SIMS WOODHEAD (London) read a paper on

Post-Diphtheritic Paralysis.

He began by quoting statistics from a large number of cases of diphtheria or suspected diphtheria in which a bacteriological examination had been made at the Conjoint Laboratories, with the object of showing the large proportion of cases in which paralytic phenomena developed. The distribution of the primary paralysis was as follows. Out of 494 cases 185 were primary paralysis of the fauces, 197 of the oculo-motor muscles, 10 of other muscles, and 102 of primary paralytic heart failure. In regard to the time of onset important observations were made. Of the paralyses of the palate the great majority occurred between the fifth and fifteenth days; none before the fourth. Of the oculo-motor paralyses the bulk occurred between the fourth and seventeenth days; none before the fourth. Of the paralyses of other muscles about one-half occurred between the tenth and fourteenth days; none earlier than the tenth. Of the cardiac paralyses the bulk occurred between the fifth and tenth days, and in a few instances as early as the second day. In each of these groups the onset of the paralytic symptoms might be delayed for many days. It was obvious, however, that in the human subject the bulk of the paralyses occurred at a comparatively early date and cardiac paralyses earliest of all. The fact that the heart might be affected so much earlier than the other muscles appeared to indicate that the primary lesion probably occurred in the nerve-cells. These lesions were easily overlooked, because the changes were transient except in those cells which were completely degenerated. Sidney Martin, Meyer, and others had described segmental degeneration of the motor nerves, but in all probability such changes were of a Wallerian type. The toxin acted primarily on the nerve-cells which either degenerated or recovered at an early date; later the nerves for which these cells acted as trophic centres showed secondary degenerative changes, and only then was the paralysis revealed. After experimental inoculations of guinea-pigs for the purpose of testing antitoxins, paralyses occurred more frequently than before, probably owing to the larger doses of toxin and antitoxin now employed. Madsen, who used the original method of testing—i.e., neutralising with one-tenth of an antitoxin unit—found that most of the cases of paralysis in guinea-pigs developed at the end of the third week. He pointed out that the paralysis, when it did occur, followed the local infiltration which resulted from the injection of an incompletely neutralised dose of toxin. It began in the posterior part of the trunk and in the hind limbs. Later the symptoms became more pronounced and the paralysis gradually extended forwards to involve the fore limbs also. The muscles of the head and neck were the last to be affected. In spite of the extreme muscular weakness the animals were still very lively and continued to eat as long as there was food within reach. Ehrlich, on the

Digitized by Google

other hand, observed that the bulk of the paralyses in guinea-pigs appeared at the end of the second week, but his observations were made on animals in which the neutralising amount of serum was one unit. In this connexion it was important to note that the diphtheritic poison was a highly complex body and appeared to include several substances possessing different properties: (*a*) a substance possessing lethal activity; (*b*) a locally irritating body; (*c*) albumoses which produced a marked reaction on the body temperature; and (*d*) a substance which had a special action on nerve-cells. Now, some of these substances combined with the antitoxin only after the lethal and locally acting toxins had been neutralised, and this was especially the case with the substance which produced paralysis. Hence the larger the total doses of toxin and antitoxin employed the greater would be the risk of some of the paralysis-producing substance being left over. In other words, there were more cases of paralysis when a theoretically ten times lethal dose was neutralised by the corresponding amount of antitoxin than when unit doses were used, and still more cases of paralysis when 100 times the theoretically lethal dose was used. The author's observations also showed that the amount and severity of the local swelling was no indication either of the probability of the occurrence of paralysis or of the rapidity of its onset.

Dr. MOTT (London) congratulated Dr. Woodhead on his valuable contribution to a subject of great interest and importance. He suggested that the diphtheria toxin acted in the first instance on the most vulnerable parts of the neuron—i.e., on the fine branching filaments of the dendron and on the terminations of the axis cylinder process. These parts were bathed in lymph and therefore specially exposed to the action of irritants diffused throughout the body. He had examined cases of diphtheritic paralysis in man and had found degenerative changes in the heart without degeneration of the vagus nerve. He thought the early cardiac failure was due to the effect of stress. The weaker the heart became the faster it had to work and it would therefore more readily succumb to the action of the toxin.

Professor BAGINSKY (Berlin) said that he had been led by his own observation to believe that cases of post-diphtheritic paralysis were less common than before. He had found advanced degenerative changes in all parts of the nervous system, including both nerve-cells and nerve-fibres. The muscular tissue of the heart and diaphragm showed also extreme degeneration. He thought that cerebral embolism was the most common cause of post-diphtheritic hemiplegia and said that such cases should not be included among the true diphtheritic paralyses. He thought that antitoxin treatment should be practised as early as possible in order to reduce the number of cases of paralysis in diphtheria.

Dr. GOODALL (London) said that cases of post-diphtheritic paralysis were undoubtedly more common than before, because under the antitoxin treatment the patients either recovered or lived longer. The number of fatal cases, however, had greatly diminished. Moreover, if antitoxin be given at a sufficiently early stage, the number of cases of paralysis would be lower instead of higher than before. In a number of cases of post-scarlatinal diphtheria in the Metropolitan Asylums Board's Hospitals the proportion of those affected by paralysis was considerably less than among the diphtheria cases admitted from outside in the same time. The former series of cases were under skilled observation from the beginning and in them the antitoxin treatment was commenced at an early stage.

Dr. SIMS WOODHEAD, in reply, said that he was now convinced that antitoxin by itself had no power of producing paralysis even in large doses. He believed that the heart failed most readily and earliest because it was the organ which had least rest. He had advocated this cause in his article on Tetanus in Clifford Allbutt's "System of Medicine." Overwork and malnutrition were the great factors even in those paralyses which appeared later. The poison did its work, but it was only when muscle and nerve were called into functional activity that the full extent of the damage was revealed. The practical outcome of the whole discussion was that the antitoxin should be used early, before degenerative changes had occurred, and that a sufficient dose should be given to neutralise not only the lethal action of the toxin but also its local and its paralysis-producing action.

Dr. J. LORRAIN SMITH (Belfast) read a paper on the

Pathological Effects of Breathing Oxygen at a High Tension.

Previous observers had noted that when animals were compelled to inhale oxygen at a greatly increased tension a series of changes were produced which were partly functional—e.g., respiratory and circulatory disturbances—and partly of the nature of tissue degeneration. Bert in particular found that special effects might be produced in the nervous system resulting in well-marked convulsive or tetanic symptoms. In his own experiments on mice and small birds Dr. Lorrain Smith investigated the tissue changes which develop prior to the strychnine effect. At an oxygen tension between 70 and 80 per cent. of an atmosphere about 50 per cent. of the animals died in about a week. At 130 per cent. mice invariably died after an average exposure of 64 hours with a pneumonic condition of the lungs characterised by intense congestion and an exudate into the alveoli which was either fluid or granular, but not fibrinous, and which affected the whole lung simultaneously. At 180 per cent. death occurred very uniformly in about 24 hours, and at 300 per cent. the duration of life might be reduced to 5 hours. It was also noted that the absorptive power of the lungs was seriously impaired by exposure to high oxygen tension. At 300 per cent. small birds became very excited and in about ten minutes showed violent tetanic symptoms. It was found that this convulsive effect was not produced in birds by an oxygen tension of less than 270 per cent., whereas mice did not begin to show it until a tension of 450 per cent. was attained. The strychnine effect in birds was further found to depend upon the integrity of the lung tissue; for birds with damaged lungs react like normal mice, so that the onset of tetanic symptoms did not appear until a tension of 450 per cent. was reached. That this effect depended entirely on the tension and not on the quantity of oxygen in the blood was also shown by mixing carbonic oxide with the oxygen at different tensions, when it was found that the tetanic symptoms developed at the same tension as before. Hence it was concluded (1) that an oxygen tension of 80 per cent. and upwards would produce a pneumonic condition in the lungs of small birds and mammals and (2) that tetanic symptoms were developed at a tension of 270 per cent. in birds and at 450 per cent. in mice, and that their onset was independent of the quantity of oxygen in the blood but depended on the tension alone.

PHARMACOLOGY AND THERAPEUTICS.

WEDNESDAY, JULY 27TH.

Diseases of the Stomach.

After Dr. AFFLECK'S introductory address (which was published in THE LANCET last week) a discussion was commenced upon the Treatment of Diseases of the Stomach as relating especially to—(*a*) general treatment and diet; (*b*) the influence of drugs upon the gastric chemical processes; (*c*) the influence of the treatment of coexisting maladies; and (*d*) the indications for surgical treatment. It was opened by Dr. HERSCHELL, who mentioned that perhaps the most difficult disease to treat was atony. The indication was to improve nutrition. Electricity was valuable especially if employed as shocks from an induction coil having a very thick primary wire and a very slow make and break. Hydrotherapy was useful, and so was lavage and douching of the stomach with alternately hot and cold water. Care must be taken in washing out or douching the stomach to avoid over-distension. This was to be attained by using a double tube with the efferent tube of much larger calibre than the afferent. The douche should be continued for 5 minutes, varying the temperature from hot to cold every 60 seconds. As for dietetics in hyperchlorhydria theoretically a proteid diet was indicated, but it did not succeed in practice, for the very fact that hydrochloric acid was necessary for the digestion of proteids in the stomach seemed to increase the already too free secretion of that acid. Therefore he recommended a carbohydrate diet predigested and neutralisation of the acid with alkalies. He did not much believe in artificial digestive ferments, with the exception of taka-diastase. As to drug treatment he had found very weak solutions of tannin useful in hyperchlorhydria.

Professor EWALD (Berlin) followed. After thanking the Association for the honour they had conferred upon him, he said that rational therapeutics were impossible without exact diagnosis. Purely local treatment was not enough. Referring to modern methods of diagnosis he mentioned the gastro-diaphane as being of great value. In cases of neurasthenic dyspepsia he relied chiefly upon treatment calculated to improve nutrition generally, such as electricity and massage. Passing to the subject of gastric ulcer he said that on the

Digitized by Google

whole it was a most satisfactory disease to treat. Rest in bed was paramount if acute symptoms were present. Nutrient enemata were to be given with a little ice by the mouth for five days or so. After this a small quantity of food might be given by the mouth, and if this did not cause pain it might be continued. As to hysterical vomiting in that form which depended upon cramp of the pylorus and which was very intractable, the only thing to be done was a gastric enterostomy. Speaking of the surgical treatment of malignant disease Professor Ewald said our results were better than formerly because the disease was diagnosed earlier, but the mortality was still too high.

Dr. SAUNDBY (Birmingham) urged the necessity of rest in even slight degrees of gastric disease. It should be accompanied by massage to prevent weakness and to keep up the nutrition of the muscles. He wished to enter a protest against the indiscriminate prescribing of whisky in dyspepsia. It was an irritant and did more harm than good. With regard to gastric ulcer diagnosis was impossible in the absence of hæmorrhage. He did not use rectal feeding unless there were hæmorrhage, but kept the patient in bed on a liquid diet for the first day or so, gradually making it more and more solid.

Dr. LAUDER BRUNTON (London) said that one remark of Dr. Herschell had cleared up for him what had long been a difficulty—namely, why sometimes a bitter like calumba seemed to do good and at other times infusion of gentian. He now supposed that in cases of hyperchlorhydria the gentian would succeed better because it contained tannin. The giving of bicarbonate of soda might in some cases help in the diagnosis of gastric ulcer. If the patient were told to put a drachm of bicarbonate of soda in a tumbler of water and sip it slowly many cases of gastric pain would be relieved. If the pain were not relieved the case was not one of ulcer. It was as well to administer the bicarbonate of soda in lime water to lessen the chance of provoking hæmorrhage.

Professor F. B. TURCK (Chicago) read a short paper upon his method of diagnosis and treatment of gastric disorders. He advocated what he termed pneumatic gymnastics—i.e., distending the stomach with air, hot or cold, moist or dry, or mixed with some nebulised drug such as oil of cloves. The alternate distension and contraction of the stomach on escape of the air was of service in improving the muscular tone of the viscus. The stomach must be thoroughly cleansed and the best way to do it was by means of the gyromele or revolving sponge-brush.

After the discussion was over Dr. TURCK gave a demonstration of the various instruments and methods which he employs. The demonstration, which was very interesting, was largely attended.

THURSDAY, JULY 28TH.

The subject for discussion was

The Treatment of Chronic Renal Diseases,

which was opened by Dr. NESTOR TIRARD in a paper of which the following is an abstract.

For the purposes of the present discussion it may be convenient to divide the subject of chronic renal disease according to broad pathological lines under the headings of chronic nephritis, renal cirrhosis, and lardaceous disease. In chronic nephritis there is a tendency to the occurrence of subacute attacks with small provocation. Patients who have been passing a fairly large amount of albumin in urine of almost normal specific gravity may from time to time pass blood, and the appearance of the urine might, in the absence of history, lead to a diagnosis of acute nephritis. Hygienic treatment, therefore, has largely to be directed towards diminishing the risk and frequency of these subacute attacks, and there is very little doubt that these risks may be diminished by the avoidance of exposure to sudden alterations of temperature, and much may be done by clothing in non-conductors which readily absorb moisture and from which evaporation proceeds slowly. Patients should, so far as possible, guard against business anxieties and worries, and against late hours and other forms of excess. In considering the dietary of patients with chronic nephritis or with renal cirrhosis it must not be forgotten that patients frequently suffer from dyspepsia and distaste for food. A small quantity of alcohol, preferably in the form of a pure spirit, is useful, while for diet milk, fish, or fowl may be given. Of all diuretics the very best is water. Hæmaturia requires rest in bed and warmth. Astringents, though sometimes useful, are very liable to interfere with the digestion. For dropsy we have diaphoretics, diuretics, and hydragogue purgatives. In the first class are the various forms of hot-air baths and wet packs and pilocarpine. This last must be used with the greatest caution in cases of weak, dilated, or fatty heart, and if used at all under such circumstances must only be so as the starting-point for diaphoresis. In cirrhosis of the kidney treatment has to be almost entirely symptomatic, but the nitrites are useful in relieving tension. For sleeplessness opium may be given with caution, though hyoscine is to be preferred. Sulphonal is also useful. For acute attacks of uræmia nitrite of amyl is often efficacious; chloroform must be given with great caution. In uræmia occurring in acute nephritis purgatives and diuretics are useful, but in the uræmia of chronic nephritis they are not so useful as there is so little kidney substance to work upon.

Professor EWALD (Berlin) read a paper on the Benefits to be obtained by Venesection and repeated Tappings. He used rather larger tubes than is customary in this country. Venesection, however, must not be used for those patients who had a weak pulse.

Dr. J. BARR (Liverpool) considered that the amount of albumin did not matter much. What was important was the amount of effete matter retained. He advocated an exclusively milk diet and considered pilocarpin most dangerous.

Dr. D. C. MCVAIL (Glasgow) said that the estimation of the urea was very important. *The* diuretic was water, aerated for choice, and if patients exhibited a distaste for it salines were to be given, and the best saline was common salt. He allowed milk, fish, and chicken. Opium might be given with safety, and pilocarpin was most useful.

Dr. SAUNDBY (Birmingham) also considered that the diet need not be strictly confined to milk. For uræmia he employed a brisk purge, the hot-air bath, and large enemata of cold water. For uræmic dyspnœa erythrol tetra-nitrate was often useful.

Dr. C. J. MACALISTER (Liverpool) wished to draw attention to the use of oxygen inhalations in uræmia. They seemed to increase both the amount of urine and the amount of urea. Pilocarpin was a dangerous drug if the patient was unconscious owing to the risk of setting up œdema of the lung. Opium and its preparations were, he thought, quite allowable in cases of uræmia where the pupils were dilated, but if they were contracted hyoscine must be employed.

After the discussion Professor EWALD and Dr. HERSCHELL gave a demonstration of Intra-gastric Instruments, and Dr. TURCK repeated his demonstration of Wednesday.

LARYNGOLOGY AND OTOLOGY.

WEDNESDAY, JULY 27TH.

Introductory Remarks.

Dr. PETER MCBRIDE (Edinburgh), President of the Section, said the best literature on Laryngology came from journals from Germany and France. New remedies are too often praised by the inventor in whose hands only they are successful. Laryngologists are human. It is necessary for every specialist to keep pace with the literature of his subject. It falls most hard upon lecturers and writers of text-books to do so. Abstracts of papers are a great help, but they are not always correct representations of what the author wishes to convey. A leading specialist can hardly accept one single author as his guide. Only papers of great use ought to be abstracted and published in English or French from foreign journals. Specialists are apt to magnify the importance of their speciality. He referred to an undue therapeutic credulity and to the glut of literature. Although there is much that is good there is more that is valueless. The amount of literature bears heavily upon conscientious readers. He suggested that a committee should be formed by the best-read men in the literature of the subject; they should decide which papers ought to be abstracted, and that there should be a staff of younger men working under their direction as abstractors and their abstracts should be supervised by the committee in this way.

The Mutual Relationship and Relative Value of Experimental Research and Clinical Experience in Laryngology, Rhinology, and Otology.

This discussion in its particular bearing on laryngology was opened by Sir FELIX SEMON (London), who began by describing the discrepancies of opinion concerning this question at present existing amongst laryngologists and humorously

Digitized by Google

depicted the gradual shades of opinion, from the extreme right wing, the "stern unbending Tories," representing those clinical laryngologists who did not believe in the value of experimental research at all, to the radical left, or the "stalwarts" of experiment, who looked upon clinical experience as mere "bag and baggage." He himself confessed to belong to the "centre" party—i.e., those who from experience of their own had arrived at the conclusion that methods properly applied are extremely valuable. This thesis the speaker supported by a rapid survey of the achievements, the failures, the applicability, and the sources of error of each method. It was first shown by a series of illustrative examples that the clinical method, whilst usually most successful in determining not merely the nature of most local affections of the larynx, but also of grave constitutional disease in distant parts, yet in not a few instances did not suffice for the establishment of a positive and certain diagnosis, and that in other cases even when showing the nature of the disease it did not give an explanation of its causation. It was further pointed out that even the employment of all modern accessory methods of investigation (microscopy, electricity, bacteriology, &c.), did not afford guarantee of an absolutely reliable conclusion in many instances. Hence the desirability of further help in that respect was unreservedly admitted, and the importance of experimental research in view of thé progress obtained by its employment in so many other branches of medicine was duly emphasised. At the same time the question was asked whether its results so far as obtained with special regard to laryngology had been of so universally reliable a character as to justify its laying down the law to clinical laryngology. In reply to this the principal experiments referring to special laryngological subjects were passed in review, and it was shown (1) that the applicability of experimental research in laryngology had been so far very limited; (2) that in certain instances its results had undoubtedly been decisive and of great importance to clinical progress—e.g., in the question of extirpation of the larynx, of the special representation of the larynx in the cerebral cortex, of the existence of the reflex-tonus of the dilator muscles of the glottis during quiet respiration, &c.; (3) that, on the other hand, its employment had in various questions not only not cleared up previously existing difficulties, but had on the contrary increased them; and (4) that the experimental method had so far failed in elucidating some of the fundamental laryngological problems—e.g., the question of the ultimate origin of the recurrent laryngeal nerve, the question whether this nerve contained centripetal fibres, &c. In continuation of this argument it was pointed out that in purely pathological experiments—i.e., in the imitation of pathological processes by experimental research—the results had been even less satisfactory, inasmuch as in the two most important attempts of the kind which have so far been made —Krause's attempt to experimentally imitate the pressure of a growth upon the recurrent laryngeal nerve and Klemperer's injection of pathogenic micro-organisms into the laryngeal areas of the cerebral cortex—the results had caused an augmentation rather than a diminution of the discrepancies of clinical observers on these important points. The speaker endeavoured to explain this by enumerating the various and grave sources of error in experimental research with which he had become personally acquainted and from this drew the conclusion that there were four general principles which ought always to be remembered when experimental research was resorted to for the solution of laryngological problems—viz: (1) what was the question to be solved? (2) what was the method of the experiment undertaken for its solution? (3) what were its possible or probable sources of error in the individual case? and (4) who was the experimenter? In support of these propositions he pointed out (1) that not all questions in which the help of experimental research was invoked were equivalent and equally suitable for experimental investigations; (2) that there were enormous differences between the methods of various experiments; (3) that the sources of error encountered in certain experiments were so manifold and so great as to entirely spoil the application of their results to apparently analogous conditions in man; and (4) that a rare combination of qualities was required to make a successful experimenter. The conclusion ultimately arrived at was a reaffirmation of the speaker's conviction expressed eight years ago in the *Virchow-Festschrift* and couched in the following terms:—"Many years' clinical and experimental investigation leaves no doubt in my mind that in these questions experiment cannot lay down the law to clinical observation or clinical observation to experiment. I feel equally certain there is no incompatibility between them, that the one completes the other, and that whenever a contradiction seems to arise the conflict is only *apparent*. With sufficient patience and care it can always be traced to defective clinical or pathological anatomical observation, to faults in the experimental method, or to an incorrect way of stating the problem."

Dr. MILLIGAN (Manchester) dwelt at some length on streptococci and pathogenic infection and also referred to the value of Dr. Koch's researches. He touched on the importance of purulent discharge from the ear, otorrhœa and diseased bone, and said that we should go carefully into the exact etiology, whether lymphatic, vascular, or tuberculous, or by direct means of infection. He dealt at some length on adenoid growths being tuberculous, the frequency of tuberculosis in them being, he found, 7 per cent.; others had reported 3 per cent. He thought it pointed to the fact that adenoid masses gave rise to and spread tuberculosis. We knew too little of the spread of tuberculosis from adenoid masses and catarrhs of the upper air-passages. We should have (1) a knowledge of the production of disease from these sources, and (2) of the ultimate result of mastoid circulation suppuration. (He showed a specimen illustrating tuberculosis from adenoid masses.)

Dr. DUNDAS GRANT (London) remarked upon the unanimity of opinion of all who had listened to Sir Felix Semon's and Dr. Milligan's observations, and referred to Cheyne's work as a perfect monument to his fame and to his experiments on rabbits; by stopping up the nose of young animals he produced growths, atrophy, and curvature of the spine. He referred also to Dr. Cresswell Baber's case before the Laryngological Society of London touching on these experiments. Dr. Grant had also found that the atrophy, &c., took place on the wrong side. He thought the discussion was good and well worth being brought forward.

Dr. ST. CLAIR THOMSON (London) agreed with Sir Felix Semon and Dr. Milligan. He himself had had a case which did not come up to Sir Felix Semon's observations. He mentioned the experiment of an American authority on animals exposed to very bad air, who explained his results as proving that "individuals" were not any the worse for inhaling sewer air. He referred to Dr. Schaffrey's experiments with bacilli in a test-tube exposed to sewer air, the bacilli were not rendered more or less virulent by exposure to sewer air. He also referred to infections of the Eustachian tube and to the fact that the serum of the nternal ear was sterile prior to perforation of the tympanum.

DISEASES OF CHILDREN.

WEDNESDAY, JULY 27TH.

Spinal Caries.

Mr. VICTOR HORSLEY (who was unable to be present) sent a paper on the Treatment of Spinal Caries. He said that the question of the best treatment of the lesion of the bones was more important than that of subsequent deformity. He held that vertebral caries should be treated in the same way as tuberculous disease of bone elsewhere and advocated early operation. There was no special risk attaching to aseptic operations on the spine. He himself had only seen severe shock after operation in the case of one child, and it could be entirely avoided by performing the operation in two stages. Some considered that operation might arouse quiescent tubercle, or the dissemination of tubercle. This he sought to prevent by free flushing with dilute perchloride lotion (1 in 5000). He took away laminæ freely and tried to remove the whole of the disease. Deformity might be altogether prevented if the operation were done early and subsequent elastic traction were maintained. The extension should be made from anklets, and from the head as well as the axilla. It was often very difficult to tell whether there were an abscess, as pain and fever were often absent. The best guide was the degree of collapse of the bodies indicated by displacement of the spines. Post-pharyngeal abscesses should be opened from the side of the neck; never through the mouth. Any inflamed lymphatic glands around the carotid could be removed at the same time. In the dorsal region it was often difficult to get at all the diseased bone and to follow up an abscess, and many laminæ should be freely removed if necessary. He had no personal experience of Calot's operation, which did not provide for treatment of an abscess, and

Digitized by Google

there was no guarantee that it would permanently relieve the deformity.

Mr. ROBERT JONES (Liverpool) said that if it were possible to get at all the diseased bone he would be able to accept Mr. Horsley's conclusions. But the examination of pathological specimens showed that this would often be impossible. He did not approve of elastic extension, as if it were strong enough to produce rigidity it would be insupportable to a small child. He strongly insisted that any support should be convex so as to produce some lordosis to prevent falling in of the bodies. Patients were quite comfortable in such a position provided that the legs were not on the convexity but lay on a flat surface. Sayre's jacket was unsatisfactory. It merely acted as a ferule, either too tight or too loose. Whatever apparatus was applied the shoulders must be well pulled back. If caries were treated by an extensive open operation there was considerable risk of septic infection subsequently. He had performed the Calot operation 93 times with 7 deaths at periods of from six weeks to nine months after operation, the same proportion of deaths as in a number of cases which were not submitted to this procedure. He believed there was a future for the operation.

Mr. R. W. MURRAY (Liverpool) had performed Calot's operation 14 times and he was bound to say that he did not approve of it. Although no accident had occurred owing to the immediate reduction the cases had not done well, and in the case of two who died subsequently it was found that there had been no attempt at repair.

Mr. NOBLE SMITH (London) thought that if patients were in good health and properly treated deformity did not often occur. Fixation by extension was unsatisfactory, and in the position of lordosis advocated by Mr. Jones there was risk of bringing inflamed surfaces of bone together. He preferred support by apparatus. Removal of the whole disease was often impossible, and that it was not necessary for recovery was shown by the progress of many cases of hip disease.

Mr. A. H. TUBBY (London) said that the treatment depended on the stage of the disease. If treated with recumbency in a position of partial lordosis till pain passed off most cases would recover without deformity. When deformity had occurred Calot's operation, although still on its trial, promised to be of great service. He himself had performed it in 29 cases.

Mr. THOMAS (Birmingham) emphasised the importance of being constantly on the look-out for signs of caries, as its onset was often insidious. The most important factor in treatment was fixation of the spine by whatever means secured. He thought that the opening of abscesses should be left as long as possible. With reference to Calot's operation he mentioned that he had trouble in one case from tendency to sores on the skin which had been formerly stretched over the boss.

Mr. F. CHURCHILL (London) spoke in favour of conservative treatment.

Mr. LUCKHAM (Salisbury) thought that when patients had the advantage of good country air operation was rarely called for. If an abscess formed he aspirated once or twice and injected iodoform emulsion. Incision was often thereby avoided, and if necessary the wound was more easily kept aseptic.

Dr. E. E. DYER (Alloa) also spoke.

Mr. H. J. STILES (Edinburgh) read a paper on the Treatment of Mastoid Disease in Infants, and pointed out that while intracranial complications are relatively less frequent in children than in adults, mastoid abscess was more frequent. He showed that the operation of clearing out the mastoid antrum in infants differed in one or two important points from that in the adult in consequence of the anatomical peculiarities of the temporal bone in the infant. On account of the absence of the mastoid process the stylo-mastoid foramen and therefore the facial nerve which leaves it is exposed to injury by the incision to expose the antrum. To avoid the nerve this incision must not extend too low down and the lower part of it must not extend down to the bone. The root of the zygoma must not be taken as a guide to the antrum, because if the bone be penetrated below this ridge the middle fossa of the skull will be opened immediately in front of the antrum.

Mr. R. W. MURRAY read a paper on Harelip and Cleft Palate, containing the results of 125 sutures. The various methods of operating were shown on the screen. Mr. Murray emphasised chiefly the value of the button suture and the desirability of closing the soft palate before the child tried to learn to talk.

Mr. MURRAY also read a paper, with many illustrative lantern slides, on the Treatment of Club Foot by Tenotomy and Tarsectomy.

Mr. A. H. TUBBY read a paper on the Occurrence of a Dorsal Pad on the Feet and occasionally in Rickets. In some the prominence was subcutaneous and semi-fluid and in some bony according to the duration of the condition.

Mr. STANSFIELD COLLIER (London) read a paper on Dislocation of the Hip-joint occurring in the Course of Infectious Diseases. Mr. Collier held that there were two types: (1) those associated with arthritis and (2) those where the dislocation was due to relaxation of ligaments with loss of tone of some muscles and over-action of their antagonists.

THURSDAY, JULY 28TH.

Mr. HUTCHINSON (London) opened a discussion on

Certain Aspects of Congenital Syphilis

and dealt chiefly with affections of the bones and the organs of special sense. He referred to the occurrence of a rare form of bone disease closely simulating osteitis deformans which sometimes occurred as a late development of the disease. He said that keratitis might occur during the first months of life, after that it was most frequent at the age of twelve, but that it might occur from the age of twenty to forty. In the latter cases there was often simultaneous syphilitic synovitis. Deafness, on the other hand, occurred solely in comparatively young patients. Arrest of mental development and partial idiocy might come on in adolescence in congenital syphilitics who had been brightest children. As regards prognosis Mr. Hutchinson thought that after showing symptoms of congenital syphilis in childhood patients usually enjoyed excellent subsequent health. He did not believe in transmission to the third generation, and thought that these patients might marry without any risk. He was still of opinion that two years was long enough for a man to wait before he might marry without risk of transmitting the disease, but it was possible that the duration of transmissibility was longer in the case of women.

Dr. HENRY ASHBY (Manchester) spoke chiefly on affections of the brain. He showed specimens in which (1) microcephaly had been the result of arrest of development from syphilitic arterial disease, the brain after hardening weighing less than 4 oz.; and (2) a brain in which idiocy was produced by syphilitic meningo-encephalitis. Syphilis was, however, by no means a common cause of idiocy.

The discussion was continued by Dr. HUDSON (New Zealand), Dr. FINLAYSON (Glasgow), Dr. JOHN THOMSON (Edinburgh), Dr. SYMES (Dublin), Professor BAGINSKY (Berlin), Professor COMBY (Paris), Dr. TELFORD-SMITH (Lancaster), and Mr. J. HUTCHINSON, jun. (London).

The following papers were read:—

Mr. ROBERT JONES (Liverpool): On the Short Leg of Hip-joint Disease and its Treatment (with lantern demonstration).

Dr. JULES COMBY (Paris): On Moveable Kidney in Children (with lantern demonstration).

Professor BAGINSKY (Berlin): On Hospitalism and Atrophy of Children (with lantern demonstration).

Dr. F. E. BATTEN (London): On Diphtheritic Paralysis (with lantern demonstration).

Dr. G. F. STILL (London): On the Micro-organism of Simple Posterior Basic Meningitis in Infants.

Dr. G. A. SUTHERLAND (London) and Mr. WATSON CHEYNE (London): The Treatment of Hydrocephalus by Intracranial Drainage.

FRIDAY, JULY 29TH.

Rheumatic Heart Disease in Childhood.

Dr. DAVID LEES (London) opened a discussion on this subject. He drew particular attention to the occurrence of dilatation in all forms of rheumatic heart disease in children. In many long-standing cases it was to the dilatation rather than the valvular lesion that the impediments of the circulation were due. He showed from extensive clinical and post-mortem records that transient dilatation was frequently to be demonstrated in children suffering from chorea or from a first attack of rheumatism without endocarditis. Tracings were shown on the screen illustrating these points. The dilatation was not due to myocarditis secondary to the pericarditis, which was so frequently present in juvenile rheumatic heart disease, for it only occurred in rheumatic

Digitized by Google

cases and was not present in pneumococcal and tuberculous pericarditis. With reference to prognosis Dr. Lees held that this depended on the amount of permanent dilatation, but that if compensation was good and the child was guarded from subsequent attacks of rheumatism the prognosis was not very unfavourable. Successive attacks of rheumatism further damaged the heart and were the most serious danger in the future.

The following members took part in the discussion: Sir WILLIAM BROADBENT (London), Dr. EWART (London), Dr. W. OSLER (Baltimore, U.S.A.), Professor BAGINSKY (Berlin), Dr. FINLAYSON (Glasgow), Dr. THEODORE FISHER (Clifton), Dr. F. J. POYNTON (London), Dr. LINDSAY STEVEN (Glasgow), and Dr. SAMWAYS (Mentone). General agreement was expressed with Dr. Lees's conclusions except by Dr. Ewart, who held that the alterations in the area of cardiac dulness were due to ephemeral effusions rather than to dilatation.

The following papers were read:—

Dr. JAMES H. NICOLL (Glasgow): The Radical Cure of Spina Bifida treated by Open Operation.

Dr. R. MARTIN (Manchester): On the Effects of Tobacco Smoking in Children.

Dr. J. KAY TOMORY (Caithness): Note on a Case of Supernumerary Testicle.

Dr. JAMES CARMICHAEL (Edinburgh): Types of Infantile Pneumonia.

DERMATOLOGY.

WEDNESDAY, JULY 27TH.

This Section was opened under the presidency of Dr. W. A. JAMIESON (Edinburgh). There was a good attendance, including several foreigners of distinction, amongst whom may be mentioned Dr. P. G. Unna (Hamburg), Professor Boeck (Christiania), and Dr. Janowsky (Prague).

The PRESIDENT, in opening the Section, after welcoming the members and visitors, sketched the history of dermatology in Edinburgh from the time when Professor Hughes Bennett first had charge of special wards devoted to diseases of the skin in the old Royal Infirmary and referred to the great changes which had taken place in the treatment of skin diseases since then. The chief part of his address was devoted to the subject of

The Application of Rest in the Treatment of Diseases of the Skin.

He inquired what is meant by "rest," which really indicated comparative rest, and referred to the views of Horace and Sophocles. Why is rest necessary? formed the text of the next part. The very term "eruption" indicates disturbance of function and hence it calls for rest. Various states of unrest as regards the skin were referred to and the demand for rest in states of over-action of the glands and appendages of the skin. Ichthyosis, seborrhœa, and hyperidrosis were considered in this relation. Hyperæsthesia and pruritus served as illustrations of another group of irritative skin lesions. The inflammatory diseases provided exemplifications from another side, such as eczema, acne, &c. Exaggerated sensibility to light might be seen in such diseases as xeroderma pigmentosa, which needed rest and protection. Lastly, ailments due to parasitic agencies were dealt with and the different modes in which rest could be procured for various forms of irritability were described.

After the presidential address the Section adjourned to the Royal Infirmary, where a clinical meeting was held for the exhibition of patients and informal discussion of the cases. The cases, which were for the most part under the care of Dr. Jamieson or Dr. Norman Walker, consisted of the following. Xeroderma pigmentoum in a girl, aged six years, which was improving under a soothing ointment and a veil and other protective measures. A sister, two years younger, had lately been developing a few freckles which looked suspicious of the disease arising in her. Two cases of sclerodermia in young women under treatment by Unna's ointment of perchloride of mercury. In one of the cases this had been combined with massage. Another case of sclerodermia round the mouth had been under treatment for a whole year by potassium iodide, 5 gr. thrice daily, without improvement. Two of these cases were undoubted cases of sclerodermia and had the characteristic lilac border which had not spread; but Dr. UNNA (Hamburg), remarking on the case of scleroderma of the lip, thought it was a more localised disease, a kind of acne keloid—i.e., a fibroma around the hair follicles of the moustache. A case of that rare condition, infective angioma, or lupus lymphaticus of Hutchinson in a man, aged twenty-six years. About fourteen years ago, while practising gymnastics, he had noticed little reddish spots on the forearm. Ten years ago, when he first came to Dr. Jamieson, the eruption presented precisely the same appearance as now. The spots consisted of dilated capillaries situated on the flexor and extensor aspects of the arm. Microscopic examination showed them to consist of thrombi at the top of the dermal papillæ. The patient had suffered no inconvenience or subjective symptoms of any kind. A case of ulerythema sycosiforme on the beard and scalp in which the eruption consisted of a keloidal condition with baldness and pustules affecting the beard. A case of adenoma sebaceum in a lad, aged seventeen years, who had been under observation for many years, was combined as usual with arrested mental development. The treatment adopted had been repeated application of the thermo-cautery, doing a small area at a time. Very great improvement had taken place both in the skin and the mental condition. Two cases of dermatitis herpetiformis; the patients had suffered for eight or nine years from vesicles arranged in groups, leaving stains and pigmentation on the arms, trunk, and legs. Both were regarded as characteristic specimens of the disease. Three cases of a condition described as an unusual variety of lichen ruber planus (of Wilson) gave rise to considerable discussion. One of them, a man, aged fifty years, who had been affected for about eight years, presented some of the characters of the lichen ruber of Hebra, and in his case some of the spots had been excised and presented the typical appearance of that disease under the microscope. The other cases appeared to present earlier stages of the same condition, whatever it might be. All three presented a universal eruption and in the most severe case the entire integument presented a crimson appearance formed of red spots which had become confluent, with small spaces of what appeared to be atrophy between.

Dr. UNNA (Hamburg), remarking on these cases, thought that they corresponded with what he had described under the name parakeratosis variegata; the distribution of the rash, the crimson colour, and the ring-like appearance of some of the spots suggested this, but the small islets of atrophy did not correspond.

Professor BOECK (Christiania) confirmed this view. He had met with similar cases which could not be classed quite with lichen ruber. He thought the atrophy was more apparent than real by reason of the swelling of the affected skin leaving healthy areas depressed.

Dr. J. F. PAYNE (London) had seen cases like these and though he had included them provisionally under lichen planus he felt that they were something different as a whole, and though the anatomy might be the same as lichen planus it did not follow that they belonged to that group.

Mr. MALCOLM MORRIS (London) thought possibly these cases might be a kind of lichenification or they might be an early phase of mycosis fungoides. A slowly progressive inflammatory condition of the skin of this kind might go on to several other maladies.

Dr. RADCLIFFE CROCKER (London) believed that these cases might probably be a variety of lichenification. Certainly their characters and distribution did not exactly resemble lichen planus, but they might be a sub-variety of that disorder as Dr. Unna had suggested. On the other hand, they might be an early stage of mycosis fungoides, though in that condition there were acute exacerbations of lymphangitis, such as these cases had not exhibited, although the patches in one case were like the premycosic stage. He was inclined provisionally to put them in a separate group, such as Dr. Unna had suggested.

Dr. ALFRED EDDOWES (London) thought much could be learned from the history of such cases and he referred to a case of "gouty eczema" which much resembled one of the cases.

A case was exhibited for diagnosis in the person of a young woman, aged twenty-one years, in whom the disease had existed ever since she was six months old. The face, legs, and trunk, but especially the legs, presented raised hypertrophic patches closely set, more or less circular or ovoid in outline, of a livid purple hue, and presenting a warty surface. Microscopic examination of the lesion showed a great overgrowth of the mucous layer of skin—a sort of acanthosis. It presented an appearance of a tuberculous

Digitized by Google

lesion in some respects and Dr. T. D. SAVILL (London) suggested that it might be a widespread lupoid growth. The age of advent and the long duration were in keeping with this. A series of cases of lupus erythematosus was exhibited presenting types of the different varieties such as the telangiectatic form undergoing improvement, an example of the exanthematic type, and several cases illustrating the difficulty of coming to a conclusion between lupus erythematosus or lupus vulgaris. A case of vitiligo in a child, aged ten years, who had had the disease for seven years. A case of elephantiasis in a girl aged fifteen years. The disease began many years ago as lupus vulgaris of the foot; it had spread up the leg and by producing lymphatic obstruction it had resulted in elephantiasis. A case of mild degree of ichthyosis in a girl, aged thirteen years, was shown to illustrate the President's remarks on the application of rest. The girl had been washed daily with resorcin-salicylic soap, and a zinc and starch paste, and had made considerable improvement.

Dr. J. M. H. MCLEOD (Dundee) showed a case of Symmetrical Paronychia in a man aged seventy-five years.

Dr. J. MACDONALD (Cupar, Fife) brought up a case of Mycosis Fungoides in a man, aged forty years, which had come on during the last two years.

MEDICINE IN RELATION TO LIFE ASSURANCE.

WEDNESDAY, JULY 27TH.

Dr. CLAUD MUIRHEAD (Edinburgh) (the President of this Section) said: For the first time in the history of this Association a section has been instituted for the consideration of

Medicine in Relation to Life Assurance,

and I think our President deserves the congratulations of the members of the Association for the happy inspiration which prompted the formation of it. For to him, I believe, the idea is entirely due. And, indeed, when one considers the matter, it is rather a surprise that the formation of this Section has been delayed so long and that only now it is taking the position in the Association to which it is fairly entitled. Before proceeding further permit me to thank those gentlemen who have the arrangement of these matters in their hands for the honour which they have conferred upon me in inviting me to assume the position of first president of this new Section. We have also to congratulate ourselves on the good fortune of having many of the leading men in this city and elsewhere who are connected with insurance offices of the first rank conjoined with us in our deliberations and discussions on the subjects which are to be brought before us. The Faculty of Actuaries have also kindly responded to our invitation to give us the benefit of their rich experience, an experience which as it is commonly built up on a statistical basis is at once final and irrefutable. I think that from such a combination of persons, whose minds are daily engaged in weighing evidence, in close reasoning, and in deducing practical results from the premises submitted to them, in conjunction with the more practical experience of our own profession, there cannot fail to arise most valuable conclusions as the outcome of our conference, which will prove of much service in guiding us more equitably perhaps, and certainly more satisfactorily to adjudicate upon the merits of cases which in future may come before us as proposals for life assurance. And if this turn out to be a correct surmise it will prove the most ample justification for the formation of this new Section, and lay the foundation for its acceptance as a permanent branch of our Association. As you are all probably well aware the business of life assurance has of late years made enormous advances, and huge sums of money are now and again set aside in this way not merely for the original humane and beneficent purpose of securing to the widow and her children on the death of the head of the house some means by which they may be saved from the terror of actual poverty, but it is also largely used for commercial purposes and more lately as a method by which to meet the demands of the Chancellor of the Exchequer when he claims the estate duties. It may astonish some of you, as it certainly amazed me, to learn that in the United Kingdom the liabilities of life assurance companies amount to no less than £263,829,625. In the statistics given in the last Insurance Companies' Bluebook it is stated that nearly one-half of the population of the United Kingdom (exactly 42·70 per cent.)—men, women, and children of all ages—is insured in some form. Now what relation to this vast enterprise does the medical profession hold? What is our position in regard to life assurance? Apart from this purely personal relation to life assurance the medical profession is and has for long been associated with the companies in enabling them to make judicious selection of lives proposed for assurance. Not much before the commencement of this century were the services of a medical man asked for. On reference to the first proposals of the Scottish Widows Fund Society in 1814 I find that the applicant had to appear before a medical man and produce a certificate to this effect—I quote the words:—"I, ..., do hereby certify that ..... mentioned in the written declaration [application form] did appear before me this day, and that I have known ..... for ..... years, and that to the best of my knowledge he hath never been afflicted with gout, asthma, or any disease which tends to the shortening of life, and that I do believe ..... present state of health to be good and his habits of living not such as to endanger ..... life. Given at ..... this ..... of ....., 18.... Signature ..... Note appended: This, or any other form adapted to the case, to be used." This not very elaborate report continued in use up to the year 1830, and it will be observed that most attention was paid to the general appearance of good health without apparently any examination of the applicant whatever. It is curious to note how concerned the directors were at that early date to ascertain if the applicant had suffered from gout. It does not appear how they dealt with a case where the man confessed to having been afflicted with gout, but evidently they were impressed with the fact that gout tended to the shortening of life, a fact which was later lost sight of and has only recently been recognised as a condition calling for a surcharge on the premium and for which our friend Mr. Meikle will at a later stage bring forward ample justification. In the year 1830 these perfunctory reports were no longer considered satisfactory, and a certificate was required from the private medical attendant, to whom a series of specific questions were addressed with regard to the general state of health of the applicant, the nature of any serious illness, suspicion of any organic affection, any injury, his habits and constitution. This report was returned to the manager or *medical officer of the society*. About this time vouchers as to character and health were required from friends. This is apparently the first time the society deemed it prudent to retain the services of a physician to aid them in the sifting of cases. And in 1835 they went a stage further and required applicants to appear before their own medical adviser, as well as to produce answers to a more elaborate set of questions as to health and family history, addressed to the private medical attendant. A report from the agent and two private friends were also called for. It would thus appear that coincident with the advance in medical science and the spreading of the knowledge of more precise means of physical diagnosis the companies sought for and obtained more exact information as to the actual condition of proposers before admitting them to the benefits of their societies. And so the process of selection of the most healthy lives has gone on to this day, each company trying from time to time to improve upon the medical forms which are placed before their examiners, in order to obtain as complete and faithful an account of the proposer as possible, both as to his family and personal history, as well as to his physical condition at the moment of application. There exists a popular belief that all this care is of little use, and that the benefits of selection are entirely lost after the first five or six years. Acting on this assumption, companies have been started to accept lives without any medical examination. But, so far as I am aware, they have not proved a success, as one would naturally predicate. For to them all the rejected of other offices would as a matter of course repair, and the healthy would equally as a matter of course carefully shun such offices. But the fallacy of this has been repeatedly exposed and by none more effectively than by our two friends Dr. Sprague and Mr. Meikle of this city, who have shown that after elimination of the voluntary withdrawals the advantages of selection diminish at all ages with duration of the policies—rapidly at young ages, slowly at middle life, while in the older it probably never entirely disappears. Mr. Edgar Holden thus defines selection:—"Of any number of persons we know how many will attain a given age, how many will

Digitized by Google

die each year, and the mathematical value of the chance of any to attain his expectancy; but to know which ones will do so is impossible. To decide which are most likely to do so is selection." And it is to the credit of the medical profession that they by their careful examination of candidates for insurance largely contributed the data which enabled the actuaries to formulate their tables of expectation of life for healthy males and thus to estimate the mathematical value of the chance of man attaining his expectancy. 'But infinitely more difficult is the problem which is constantly submitted to us—viz., how equitably to assess the value of under-average lives, how sufficiently to protect the societies against loss, and how, at the same time, not to overcharge such candidates for assurance. Here we have no fixed and mathematically correct data by which to guide our decisions; we have no aggregated groups of persons suffering from the same disorder, though perhaps differing greatly in form, which might supply a basis by which to adjudicate upon the special case before us. And if the extra rates recommended by medical officers have, in the past, saved the offices from loss, I am bound to admit that this happy result has been arrived at without the aid of any scientific formula and by merely empirical methods. Now, gentlemen, it appears to me that one of the most important functions of this Section is by our discussions, our interchange of views, the communications brought before us, and by stimulating medical officers to investigate the records of their various companies, to endeavour to devise some more scientific —I shall not say more equitable—principles to guide us in our estimate of extra risks. Our good friends the actuaries have already calculated for us the after-life of groups of *healthy males;* and if we can only supply them with sufficient data by which to calculate by how much the expectation of life of unhealthy men is diminished in special groups of disease, they would quickly provide us with a table of the expectations of *unhealthy males*, and thus our task would be immensely simplified. I do not doubt that the discussions and papers already announced to be dealt with in this Section will do much to advance and stimulate this much-to-be-desired end, and in this way to perhaps extend the boon of life assurance to those who may for the present be reckoned to be outside its pale.

The Prognosis of Cardiac Disease in its Bearings upon Life Assurance.

Sir WILLIAM T. GAIRDNER (Glasgow) in opening the discussion said: It was from the experience of general practitioners that we might hope to get the best information as to the longevity of persons suffering from heart trouble, they having the best opportunity of following cases. As time went on heart disease had come to be regarded as of less serious import than formerly. He instanced two cases—that of a practitioner known to have suffered from rheumatic affection of the heart in youth who had had attacks of angina pectoris and who died between sixty and seventy years of age of a non-cardiac disease and that of a boy who in 1862 had a very loud systolic murmur all over the base of the heart and who became a keen sportsman and is now alive and, as far as a recent casual examination went, free from murmur. In this matter the insurance medical officer was in an entirely different position from the medical adviser. The former must be on the alert for any signs indicating a flaw in the constitution of the applicant, the latter on the look-out for signs which may make an encouraging prognosis justifiable. It is always difficult in heart cases to know how to deal with the applicant directly; it is painful to refuse the man, especially if you have to give reasons. It is best to put him off with hopes that at a future time he may be accepted. What are required at present most of all are data from which to judge of cardiac cases. Cardiac cases resolve themselves into eight classes. Class 1. Where there is a well-defined abnormality of doubtful significance; roughness of sounds or prolongation and various sounds heard over the right ventricle. These are apparently often pericardial and sometimes have reference to what are found in post-mortem examinations as white patches producing no symptoms during life. The question here arose whether cases of acute pericarditis ever so far resolved themselves as to be of no consequence. There was every reason to believe this was so. Class 2. Lesions involving organic changes without disturbance of cardiac functions discovered only after examination. Delay was the only course here admissible. They should be told they were more likely to be insurable later. Class 3. Lesions of limited significance belonging to senile changes. Such cases should be told to withdraw their application with reassuring remarks or be loaded up to an almost prohibitive extent. Class 4. Cases of organic lesions producing concomitant symptoms. These must be declined. Class 5. Lesions, probably functional, with no concomitant symptoms. For instance, irregularity of rhythm. Some people exhibit this from childhood. One case of this kind was instanced which had gone on very well for thirty years. Then there are cases when the heart beats become too rapid or too slow under emotion. Even when this occurs without emotion no important lesion is necessarily indicated. A too rapid pulse was probably less important on the whole than a too slow one. Sir William Gairdner as a boy had a pulse between 100 and 120. It is now 80 at the utmost and of good quality. A rather slow pulse would appear to be a sign of good health—say as low as 60. There are no data for judging of pulses lower than this. Sir William Gairdner had counted a pulse of 18, but its owner died suddenly at forty years of age in the pulpit. He had counted lower pulses in a patient who had entirely recovered. Then there was the tobacco heart and the senile heart. The former should be deferred and the latter should be told that he showed some signs of advancing age and should be declined. Class 6. Hearts with choreic murmurs. The nature of these was not yet entirely settled. Even if they get well they were organic. Choreic patients dying had always fringes on the valves. Class 7. Large or small hearts. Of these large hearts are usually considered of greater importance than small ones. Class 8. Angina or pseudo-angina. It is often impossible to distinguish between these. Angina in the family was difficult to estimate. A case was instanced of a lady, two of whose brothers had died suddenly, who took nine months to die from senile gangrene.

Dr. SYMES THOMPSON (London) said it was easy to decide cases of definite lesions but difficult when it was not clear that serious disease existed of the heart or other parts. It would appear that a pulse as low as 32 or even 28 could go on for many years if accompanied with a quiet disposition. Slowness of pulse would appear to make a high order of activity impossible. A case, however, on the other hand, was quoted of 26 to 28 in a man who could take his part on the mountains or grouse moors. The rapid heart was very difficulty to estimate, especially under examination, an ordinary heart often simulated a dilated palpitating heart.

Dr. TYSON (Folkestone) said the condition of the heart's walls and of the apex beat was of more importance than mere murmurs. It was impossible to have a healthy heart with an abnormal beat. He quoted in respect to slowness of pulse a group of eleven men with average pulse-rate of 30 whose average age was seventy years. He complained that patients who were told that they had murmurs seldom returned for re-examination. The rate of pulse sometimes fell in healthy women after confinement. He had difficulty in estimating the value of accentuated second sound in hard-worked men.

Mr. LOW (actuary) said he was struck with the frequency of the use of the expression "I don't know" in this debate. He did not remember seeing it in any reports of applicants. Statistics only would afford a definite conclusion. He thought a good way of dealing with proposers who were not accepted was to advise them to consult their own medical men; this was usually well received. Slow pulse he did not remember seeing on the records of any insurance office.

Mr. POINTON (Liverpool) quoted 150 cases of deaths from heart disease after chorea in which 149 had multiple but slight valvular disease.

Dr. MACFIE insisted on the difficulty of prognosticating mitral disease and advocated taking the applicant into confidence.

Dr. GLOVER LYON (London) advocated the formation of classes into which medically doubtful cases might be placed, heavily loaded, with the option of from time to time presenting themselves for re-examination. In case of the doubtful signs having cleared up the insurers might be placed amongst the ordinary raters.

Dr. JAMES RITCHIE (Edinburgh) mentioned the importance of age in estimating irregularity of pulse. He pointed out that the absence of slow pulse from insurance records might be explained by the excitement of examination causing acceleration of pulse.

Mr. EASTES (London) described some varieties of irregularity of heart caused by tea, coffee, and tobacco, and advocated deferment in these cases.

Sir WILLIAM GAIRDNER, in reply, said his experience did

Digitized by Google

not extend to anyone in ordinary health with a pulse under 50 or 60 or so. It would be well in cases when there was something abnormal, impossible to explain, to make a large addition, to be taken off at a future time if the case admitted of such a course; this would be an equitable way of meeting such cases. Aortic accentuation in a labouring man indicated over-exertion which if persisted in would shorten life. In telling applicants of their diseases the truth should never be departed from, but this should not be blurted out in a manner which would give an exaggerated notion to the applicant.

Does Evidence of Limited Family Vitality call for an Advanced Rate of Premium?

Dr. JAMES RITCHIE at the outset deprecated the custom of putting small extras on account of slight defects in family history. The inherent causes of death had a structural existence, and the same structure in different individuals had a different degree of vitality. This vitality was a complex quality. Decay is hereditary both in effect and time. It was pointed out that a large proportion of the early deaths in the office with which Dr. Ritchie was connected and which was founded twenty years ago, was amongst insurers one or both of whose parents had died fairly early. The significance of the death of the parents from similar diseases was shown by instances even when these diseases were not of the specific nature of consumption—for instance, diseases of the heart or blood-vessels, kidney disease, cancer, nervous diseases, diabetes, or alcoholism. In the case of a family history of consumption it often indicated a special vulnerability to diseases other than consumption. In estimating the vitality of a family it would appear that not much importance should be attached to death in infancy, the surviving members of the family often developing into robust subjects. The usual motive for insurance is important in this relation. Not infrequently a man as he advances in years feels a failure in his powers; if, then, his parents by an early decease give evidence of an early degeneration it makes it probable that a like failure may be in progress in the applicant. The principle the speaker wished to enforce was that if there be in any families evidence of impaired vitality, whether it be in consequence of early decay of vital organs or of the liability to succumb to infectious ailments, the risk is increased and should be covered by extra premium.

Sir WILLIAM GAIRDNER said that pathology tends to prove that we have underestimated the value of flaws in family history. The offices used not to make them a bar to insurance. There is now a tendency to underrate family history. In some cases the history of grandparents and even of great-grandparents might be valuable.

THURSDAY, JULY 28TH.

Dr. CLAUD MUIRHEAD, the President, being in the chair, a discussion on

Middle-ear Disease in Relation to Life Assurance

was opened by Dr. P. M'BRIDE (Edinburgh), President of the Laryngological Section, before a conjoint meeting of that Section and the Section of Medicine in relation to Life Assurance.

The PRESIDENT in a few introductory remarks said he was of opinion that too much was made of middle-ear disease in life assurance.

Dr. M'BRIDE said the subject was limited to consideration of chronic suppuration of the middle ear. Schwartze's clinic gave only 13 deaths out of 2032 cases, or 6·4 per 1000. These statistics can be relied upon as following through the greater part of the cases. Potletzer had recommended the refusal of all cases of suppurative middle-ear disease. This would appear to be too severe. Several points were of importance in this subject. The occurrence of pain should give rise to great suspicion. The presence of granulations or polypi should entail rejection, so also should necrosis, true cholesteatoma, or occlusion of the meatus from other causes when suppuration is present and when this condition is complicated with facial paralysis. In absence of this condition we must consider: (1) the perforation is of greater importance if it be small and high up; (2) the discharge—if this is copious and fetid the case must be declined; and (3) the social position is of great importance. A favourable sign was the following: a slight not fetid discharge, care being taken to find out by probing if this condition is only apparent and that deeper-seated mischief did not exist.

Dr. THOMAS BARR (Glasgow) said the Registrar-General's reports were not reliable as to deaths from ear disease and gave no information as to the mortality amongst otorrhœal subjects. Otorrhœa, too, usually occurred in subjects younger than the generality of assured lives. If treatment did not stop the discharge the case should be declined or rated up heavily. If treatment stopped the discharge the case should be passed even if a perforation of good position and size remained, also if after operation a dry cavity remained.

Dr. PRITCHARD (London) said statistics from foreign countries were of doubtful importance. The opinion of specialists was apt to be too lenient, as fatal cases seldom came under their care. Cases for rejection were cases of pyæmia or mastoid mischief, necrosis, caries, or granulation, collections of epithelium occluding the meatus, facial paralysis, also pain referred to about 1½ in. above the meatus as indicating mastoid mischief, tuberculous otorrhœa, or malignant disease. The addition of extras could not be done by rule. Some perforations were very serious, others could be taken without extras. The question of fœtor must be settled by passing a mop. As to the age of the patients a perforation occurring in a man between forty-five and fifty-five years of age, and especially after influenza, was very serious. So also was the occurrence of a large amount of fœtid discharge. The effect of treatment was of great importance. Uncomplicated cases might be taken in careful patients.

Mr. MARK HOVELL (London) pointed out the importance of the presence of exostosis blocking up the meatus.

Dr. MACKENZIE JOHNSTON (Edinburgh) said that even a simple perforation meant a hole in a patient's armour, though it might be a very small one. A simple perforation existing in a man over thirty years of age was of less importance than one in early life.

Dr. HERBERT TILLEY (London) called attention to the probability of some mischief being left behind after operation.

Mr. CRESSWELL BABER (Brighton) urged the difficulty of deciding upon a fair extra in these cases.

Dr. WILLIAM MUIR said that out of a large experience he had only known of one death from ear disease and he thought occasional slight discharge from an ear without any complication did not call for an extra.

Mr. LOW (actuary) said the small proportion of deaths registered from ear disease compared with other diseases was important. He thought the principle of every case being taken on its own merits was unsatisfactory, as no separate case is insurable.

Dr. GLOVER LYON said that as the extra risk from these cases as a whole was so small as to call for no extra it would be best to refer all cases to specialists, and decline only the more serious, accepting the others at ordinary rates.

Dr. RITCHIE said that those cases where only a slight discharge existed without complications need not be declined.

Mr. JAMES CHATHAM alluded to the necessity of appealing to the records of the offices.

A paper was read by Dr. JOHN PLAYFAIR (Edinburgh), written conjointly with Mr. J. WALLACE (actuary, North British and Mercantile), upon

The Bearing of Pregnancy upon Life Assurance.

The chief object of the paper was to show that the extras charged at present for pregnancies were quite inadequate. The Edinburgh Royal Maternity Hospital with an experience of ten and a half years and 10,038 cases and 87 deaths shows a high death-rate under twenty years of age, a minimum death-rate at ages ranging from twenty-five to twenty-nine years, and then an increasing rate. The death-rate for married alone is least at ages under twenty years and increases steadily with age. The mortality amongst multiparæ—low at twenty-five years of age—falls slightly at from thirty to thirty-four years, and then increases. The mortality of primiparæ is much higher at all ages than of multiparæ and increases more rapidly with age. Instead of, as at present, charging a fixed extra for all ages, this being for primiparæ double that for multiparæ, the following suggestions are made: (1) an extra according to age should be charged; (2) the extra for first pregnancy should be about three times that for subsequent ones; (3) a proposal for insurance from women aged thirty years and upwards should be delayed; and (4) a proposal for

Digitized by Google

insurance from pregnant women aged forty years or upwards should be delayed in all cases.

Mr. LOW raised the question whether confinements in maternity hospitals were comparable with those amongst insured lives.

Mr. MACANDLISH pointed out the necessity of inquiring carefully into the motives of insurance in pregnant women.

Mr. EASTES suggested that the advance in antiseptics might vitiate the statistics given for application to the present day.

TROPICAL DISEASES.

WEDNESDAY, JULY 27TH.

The room placed at the disposal of the newest section of the Association proved none too ample to accommodate the large number of members interested in tropical diseases. Professor Blanchard of Paris, Dr. Osler of Baltimore, U.S.A., and representatives of many British colonies and dependencies, and of the army, navy, and colonial services, evidenced interest in the subject by their earnest attention to the papers read and by taking part in the discussions.

The PRESIDENT (Dr. Patrick Manson, London) congratulated the Association upon taking cognisance of the requirements of some 6000 of our medical brethren living abroad whose interests were centred in diseases not met with in the United Kingdom. He stated that the institution of this section dealt with work which might be divided into three classes. Firstly, the affiliation of medical men directly interested in the diseases of warm climates; secondly, the education in tropical disease of practitioners before they went abroad to commence their profession; and thirdly, the study and discussion of the diseases of the tropics.

Brigade-Surgeon-Lieutenant CROMBIE, I.M.S., read a paper of considerable length upon the

Unclassified Fevers of the Tropics

and dwelt upon those of an anomalous character.

The following members joined in the discussion: Surgeon-Major BAKER, Captain HUGHES, Captain DAVIDSON, Brigade-Surgeon-Lieutenant-Colonel ARNOTT, and Surgeon-Lieutenant-Colonel THORNHILL, Dr. SAMBON (Rome), Dr. CHARLES (Rome), Dr. COUSLAND (Edinburgh), and Dr. CANTLIE (London). The general drift of opinion was in favour of recognising ulceration of the intestine as typical of typhoid fever and the recognition of the plasmodium as the test for fevers of a malarial nature. With these excluded, however, there were many fevers as yet unclassified which were peculiar to the tropics and which deserved the closest attention. The subject of ardent fever claimed considerable attention from all who took part in the discussion, and there was a distinct inclination to doubt the fact of infection playing a part in this form of disease. It is necessary to get information from even a wider field than India before authoritative statements can be made either one way or the other.

Dr. ANDREW DAVIDSON'S (Edinburgh) paper on

The Malarial Problem in its Epidemiological Aspects

was listened to with great interest. The fact of the inhabitants of Sweden being subject to outbreaks of malaria even as far north as 66° showed how widespread is the possibility of infection by the malarial parasite. Dr. Davidson also stated that even a temperature of 13° F. below zero was not incompatible with attacks of malaria. In temperate climates it was during spring that malaria chiefly showed itself.

Dr. MANSON read a short paper on

Appearance of Pigmentation in Lymphocytes in relation to the Diagnosis of Malaria.

Dr. Manson warned observers in the tropics against mistaking the normal for the adventitious pigmentation. According to Vincent[1] the phagocytic function, as regards the malarial parasite, is performed almost exclusively by mononucleated leucocytes. With this opinion, however, Metchnikoff disagrees and explicitly states that the lymphocytes are completely passive in this respect and never phagocytic. With Metchnikoff's statement Dr. Manson agreed and holds that the lymphocytic pigmentation described by Vincent and others is a normal or physiological condition to be met with in the blood of persons in good health in temperate climates.

[1] Annales de l'Institut Pasteur, Dec. 25th, 1897.

Dr. SAMBON read a paper on

Black-water Fever

as met with in Central and West Africa. He pointed out that this fever was met with in the Southern States of America, in Venezuela and Cuba, in Sicily, Java, and various parts of Asia. Dr. Sambon is of opinion that black-water fever is a specific non-malarial fever, although it is met with in districts where malaria is likely to occur. In the blood of persons suffering from melanuria crescents and other forms of the malarial parasite are to be met with, but in Dr. Sambon's opinion the diseases are not identical. Nor, on the other hand, is melanuria due to the exhibition of quinine. This opinion is rather firmly held, more especially by the New Orleans physicians, but no convincing proof has ever been brought forward to establish the dictum.

After the paper two members of the Church of Scotland Missionary Society testified to the enormous mortality caused by black-water fever more particularly in the neighbourhood of Blantyre (Africa).

The members of the Section present unanimously agreed to a resolution to the effect that the attention of the Foreign Office should be drawn to the high mortality amongst Europeans from black-water fever in Africa, and urged the Government to send experts to investigate the disease and to make suggestions as to its prevention.

Dr. THIN exhibited a Microscopic Specimen illustrating the

Parasites of the Pernicious Malarial Fevers of British Guiana.

Dr. THIN also read a paper on the

General Characteristics of Pernicious Fevers in British Guiana

and dealt exhaustively with the pathology of the disease. He also drew attention to a feature which is rare if not new—namely, two spores attacking and becoming incorporated in a single red blood corpuscle.

Major YARR, R.A.M.C., communicated a paper on

Malarial Affections of the Eye.

This little known and much-neglected subject was handled by Major Yarr in a paper which showed an intimate knowledge of the subject and is the most earnest attempt in British medical literature to call attention to what is frequently a serious disease. Malarial eye affections, according to Major Yarr, all originate in circulatory troubles and may be conveniently classified under the following headings: (1) neuritis; (2) retinal hæmorrhage; (3) retino-choroiditis; and (4) effusions in the vitreous. Repeated attacks of malaria constituted the usual antecedent, although the development of neuritis is not unknown in pernicious attacks. Photophobia, night-blindness, and supra-orbital pain are more or less constant. Of all symptoms, however, the variations in the visual acuity form the most characteristic. It is satisfactory to know that this loss of function is in most instances restored and the passage from well-nigh total blindness to normal vision in a few weeks is a gratifying result. Retinal hæmorrhages are met with in the course of malaria in two varieties—minute and large. Microscopic examination shows these retinal apoplexies in malaria to be due to infarcts of parasites followed by extravasation. Quinine amaurosis was referred to by Major Yarr. A slight degree of amaurosis with some amblyopia is frequently present in quininism without any alteration in the normal appearances, but in severe cases, with persistently contracted fields, pallor of the disc and thready vessels are found.

Surgeon-Major J. H. TULL-WALSH, I.M.S., dealt with

Clinical Aspects and Treatment of Malarial Fever

in a lengthy paper of considerable importance.

A paper by Surgeon-Captain W. J. BUCHANAN, I.M.S., gave an account of

Epidemic Cerebro-Spinal Fever in India,

with a clinical account of three cases. Surgeon-Captain Buchanan's work was conducted with great thoroughness and care. He made preparations of the purulent matter from the brain and spinal membranes, stained some six specimens with a watery solution of gentian violet and found in all a diplococcus within the pus cells answering in all particulars to that of the diplococcus intracellularis of Weichselbaum. The paper placed on record the history of

Digitized by Google

cerebro-spinal fever as met with in the gaols of Bengal and ended with the following remarks: "Two diseases—cerebro-spinal fever and Malta fever—have thus been rescued from the *cloaca maxima* of the remittents as seen in tropical countries. That yet another as yet undifferentiated fever of a continuous type exists is my firm belief, but so far the evidence in favour of this view is too indefinite to do more than allude to the belief here. That the disease here called cerebro-spinal fever, in accordance with the "Nomenclature of Diseases," is identical with the epidemic cerebro-spinal meningitis of continental and American writers is clear, but the diagnosis of isolated sporadic cases will always be doubtful without bacteriological examination."

THURSDAY, JULY 28TH.

Mr. CONOLLY NORMAN (Dublin) read a valuable paper on

Beri-beri in Temperate Climates.

His experience of the disease was gained in the Richmond County Asylum, Dublin, where he was superintendent. In 1894 an epidemic of what proved to be beri-beri attacked the inmates of the lunatic asylum of the institution. The disease disappeared in 1895, but during 1896-97 it recurred with great virulence. In all some 534 cases are recorded and 44 deaths. Mr. Conolly Norman recounted the symptoms met with and showed that they corresponded in every way with beri-beri as met with in tropical countries. He then proceeded to state that this disease was by no means confined to the tropics, but was known to have existed in North Germany, in England (Suffolk County Asylum), in Dublin, and in the States of Alabama and Arkansas, U.S.A. On the Newfoundland coast also it had been known for some time. Mr. Conolly Norman proceeded to discuss the cause, and after combating the rice and fish theory admitted that in the year 1894 the diet of the asylum was improved, amongst other articles, by the inclusion of dried ling, imported from Newfoundland most likely. Here was a loophole for stigmatising the diet, as Newfoundland was an infected district. One peculiar circumstance was that in England, Ireland, and America it was in lunatic asylums the disease occurred, and there seemed no explanation of the circumstance. It may have been that in asylums the people were watched more carefully and therefore the disease was readily recognised, but Mr. Norman pointed out that the number of cases under treatment were so numerous that had a similar occurrence taken place elsewhere attention must have been drawn to it. He agreed with Grimm that there was an initial fever and an exaggerated knee-jerk. The latter symptom soon passed off, leaving the usual paralytic phenomena. The question of parasitic infection was also discussed, but after careful investigation only negative results were obtained. No specific treatment was known; change of residence, however, was essential. A number of illustrative photographs were shown.—Dr. OSLER, Dr. MANSON, and Dr. CANTLIE joined in the discussion.—Dr. OSLER stated that cases of beri-beri were still met with amongst the Newfoundland fishermen, and that at the United States ports patients suffering from beri-beri were imported from Cuba.—Dr. MANSON believed that many cases of so-called peripheral neuritis in Britain were really beri-beri and that as the disease became better known no doubt what at present were obscure paralytic illnesses might prove to be beri-beri.

Dr. SANDWITH (Cairo) gave an account of pellagra as it occurred in Egypt. It was only in recent years that it had been recognised as existing in Egypt although no doubt it had existed previously. Dr. Sandwith claimed that it was the same disease as the Italian pellagra and that it arose from the same cause—diseased maize. The time of year during which it mostly prevailed was after the crops had been gathered, from November until March, when the new meal was consumed. Although the name pellagra meant "rough skin," still it was by no means a skin disease, but rather a general or blood disease which, commencing with erythema, goes on to hypertrophy and then atrophy of the exposed parts of the skin. It is accompanied by bald tongue, intense dyspeptic symptoms, loss of weight, and a mental and physical depression of marked intensity. Amongst other noticeable phenomena were pronounced backache and a localised deep-seated pain in the neighbourhood of the sixth dorsal vertebra. Many cases of pellagra end their days in the lunatic asylum, becoming melancholic, demented, or suicidal. Pathological evidence showed general emaciation, atrophy of most organs, and a sclerosis of Goll's column and the posterior pyramidal tract. In regard to treatment Dr. Sandwith recommended: rest, mixed diet, avoidance of even good maize, cod-liver oil fresh bone marrow, and zinc ointment for the skin.

Dr. SANDWITH also read a paper on Acute Dysentery. He advocated treatment by the sulphate of magnesia plan, and strongly urged the efficacy of an enema of sulphate of copper, 15 gr.; tincture of opium, 15 min.; starch, 1 oz.; and water to 2 pints.

Dr. OSLER (Baltimore) spoke of the benefit at times derived from rectal injections, but pointed out that the pain and exhaustion, sometimes induced, annulled its use in many cases. The great element in treatment seemed to be to keep the intestine clean, whether by rectal injections or by intestinal antiseptics administered by the mouth.

Dr. BENTLEY (Penang) advocated salol as a powerful agent in the treatment of acute dysentery.

Dr. OZANNE (British Guiana) gave it as his opinion that no two cases of dysentery required the same treatment, but that each case had to be considered separately.

Dr. PRENTICE (Central Africa) stated that in his experience ipecacuanha in large doses answered well in the part of Africa in which he resided.

Major DAVIDSON, R.A.M.C., considered that no one system of treatment was wholly efficacious at all times and that the first essential in the study of this disease was its pathology.

Brigade-Surgeon-Lieutenant-Colonel CROMBIE held that there were many cases of catarrh of the bowel with dysenteric looking stools which were not true dysentery and in these ipecacuanha was useless; but in cases of dysentery with ulceration extending as high as the cæcum ipecacuanha was most efficacious.

Sir JOSEPH EWART (Brighton) said that he was in India at the time when the paper written by Dr. Docker recommending the treatment of acute dysentery by large doses of ipecacuanha was commenced. It fell to his lot to compile the statistics of the European and native armies of India with a view to testing the results of the ipecacuanha treatment. The figures showed a remarkable reduction in the death-rate of the disease by the administration of this drug. Ipecacuanha, he considered, relieves congestion, diminishes peristalsis, and allows of rest to the injured mucous membrane. He also claimed, as one of the chief advantages gained by the exhibition of ipecacuanha, that sequelæ, such as chronic dysentery and liver abscess, were largely prevented.

Inspector-General TURNBULL, R.N., read a paper on Insanitary Environments the Cause of the Spread of Yellow Fever and the Bubonic Plague. From numerous sources, chiefly derived from naval medical reports, Inspector-General Turnbull argued that environment was the immediate cause of yellow fever, and that whenever improved sanitation supplanted a wholly insanitary state yellow fever disappeared. As an illustration of how environment acts the following instance was cited by Inspector-General Turnbull. H.M.S. *Bristol* at Sierra Leone on Dec. 28th and 29th, 1865, detailed a party of 112 men and 4 officers to unmoor and shift H.M. storeship *Isis*, a notoriously yellow fever infected ship. 38 cases of yellow fever resulted with 23 deaths; all were treated on board the *Bristol*, but no medical officer or attendant contracted the disease which was strictly confined to those who worked on board or visited the infected storeship *Isis*.

THE PATHOLOGICAL MUSEUM.

FIRST NOTICE.

The ordinary medical school museums contain in many instances admirable and varied specimens, but it is on occasions such as this that the opportunity arises for collecting a series in illustration of one topic, such, for instance, as was done at Edinburgh in connexion with cerebral tumours, injuries to the elbow-joint, and diseases of the appendix vermiformis. Since the Association met in London never has there been such an excellent collection of museum exhibits. Exhaustive and up to date in a high degree, this collection has been arranged with the greatest judgment and care and much praise is due to the energy and knowledge which Dr. Alexander Miles and Mr. C. W. Cathcart, under the chairmanship of Sir John Struthers, have brought to bear on their task. The exhibits are classified into six groups or series—educational, surgery and allied sections, medicine and allied sections, obstetrics and gynæcology, bacteriology and pathology, and drawings and photographs. It will be impossible to do justice to this exhibition in one notice so we propose to discuss the educational and surgical series

Digitized by Google

on this occasion, leaving the medical and other exhibits—which include a remarkable series of specimens of intracranial tumours—to be noticed hereafter.

NEW METHODS OF PREPARING CASTS.

One of the interesting features of this museum consisted of the fact that several new methods of making casts or models for educational or surgical purposes were introduced to the profession, and the results of several methods for the preservation of the colour in wet specimens were made known. For the new methods of modelling we are indebted chiefly to Mr. Cathcart (Edinburgh) and Dr. Peters (Toronto). The first-named uses new materials for the model and the last-named new material for the mould. Mr. Cathcart, to whose ingenuity is due one of the handiest and cheapest of the microtomes in general use, has employed as a basis for the casts three different compounds: 1. A mixture of pipeclay and glycerine in proportions to form the consistence of putty. A cast in plaster of Paris is first taken of the limb in the usual way and into the mould thus formed the pipeclay-glycerine compound is poured after being melted by gentle heat, and it is wonderful what a lifelike model is thus procured. Vermilion and other pigments can be used. 2. Papier-maché may also be used in place of the pipeclay mixture. For this process Robosal blotting-paper is torn in pieces, thoroughly softened with thick ordinary flour-and-water paste, and worked into the mould (previously covered with paraffin or vaselin) with the fingers or a dry brush, each piece overlapping the preceding one. 3. The gelatin compound simply consists of No. 1 gelatin mixed with a minimum of water to soften it and then glycerine is added ounce for ounce of hard gelatin. It forms an elastic material of lifelike consistence and appearance. Still experience makes us doubt whether the gelatin will not shrink in process of time; but we saw a model of a foot made by Dr. Miles some five or six years ago which had not contracted at all. All these three materials are very simple in their preparation and use and teachers will doubtless find them very useful. The gelatin models can be coloured with various pigments and the addition of a little oxide of zinc gives a truly lifelike representation of the human skin, as might be seen in a cast of the thorax taken in a case of dislocation of the sternal end of the clavicle.

Several very beautiful plaster-of-Paris models, made by Dr. Peters by an entirely original method, were exhibited. As a rule plaster-of-Paris casts only exhibit the gross outline of parts, but by this method the minutest details of the feathers of a bird, the veins of the back of the hand (which are generally emptied by the weight of the plaster when employed in the ordinary way as a mould), the viscera of a rabbit laid open, and all the smallest details can be seen. The novelty consists in making the mould of hard paraffin. The process is as follows. First, the parts are spread with a mixture of starch and alcohol, to which a trace of glycerine is added; then, by means of a special apparatus for melting hard paraffin wax, and ejecting it in the form of a spray while liquid, the whole is sprayed first with the melted paraffin and then with a mixture of paraffin and water. Over the top of this plaster of Paris is spread and pressed on to the outside. This forms a mould, the inner surface of which consists of hard paraffin which has taken all the fine details. It is removed in the usual way and wet plaster-of-Paris is spread or poured upon the inner surface so that a very perfect model results.

Among the educational series are specimens on a gigantic scale of the embryo and its development and some dissections of the latter.

Dr. Dawson Turner exhibited x ray photographs of brains, hearts, and kidneys, which had been injected with opaque material (? mercury) and thus the whole circulation in the organ could be seen at one time by means of an arrangement for binocular or stereoscopic vision.

PRESERVATION OF COLOUR IN WET SPECIMENS.

It has long been a desideratum to preserve the colour in wet pathological specimens. One method shown was that of Sir John Struthers, by means of glycerine and carbolic acid. The specimen is soaked in this and then simply laid in a glass case exposed to the air. An example of transposition of the viscera thus prepared in 1889 was exhibited by Dr. Harvey Littlejohn (Edinburgh) and it has in a great measure preserved its post-mortem colours. Mr. James Simpson exhibited some useful methods for mounting specimens on coloured glass, adjusting the label or a description cut out of the catalogue within the jar, methods of casting in gelatin, and preserving the colour of wet specimens. Dr. Shennan exhibited an excellent series of specimens to illustrate Joré's formalin method for preserving the colour of wet preparations. Kidneys seem specially adapted for this method, but some beautiful preparations of acute miliary tuberculosis, ulcers of the intestine, intraventricular hæmorrhage, and septic abscesses in the kidney prepared in June and July, 1897, prove that this is undoubtedly a most successful process. The wonderful way in which the natural appearance is preserved was to be seen in a series of exhibits by Dr. Littlejohn of 9 cases of cut-throat and 3 stomachs taken from cases of carbolic-acid poisoning. These specimens had simply been soaked in the formalin solution and then placed upon cotton-wool in a glass jar, at the bottom of which was a small quantity of glycerine and formalin to preserve the moisture. The jar was then loosely covered.

SURGICAL EXHIBITS.

A series of 24 vermiform appendices removed by Professor Annandale and 13 by Dr. Miles, all for inflammatory conditions, were interesting as showing once more the usual history of appendicitis and emphasising again the apparent uselessness of this little structure. The frequency with which cherry-stones, toothbrush bristles, and other foreign bodies lodge there is surprising. Six specimens of excision of the cæcum and colon were shown by Dr. F. M. Caird. All were for carcinoma and all recovered from the operation. Several are still living; some have died from other maladies. It is worthy of note—at a time when, as one of our facetious American colleagues once remarked, "Murphy's button is in everybody's mouth if it is not in his abdomen"—that an end-to-end or anastomosis operation was done in all of these cases without button or bobbin of any kind. This is a feature of the Edinburgh School.

The surgical exhibits were extremely numerous and interesting and we cannot mention them all, but a collection of over 60 cases of various injuries in or around the elbow-joint merit special notice. Nearly every kind of injury and disease in this region found a place. One lesson which they teach is this, that in resection of the joint after injury the bones should be more liberally removed than is generally done. The subject was under discussion in the Surgical Section and was reported in THE LANCET of July 30th, p. 294. A collection of 418 calculi removed from the bladder (404 by crushing and 14 by lithotomy) during 11 months in Hyderabad, Sind, exhibited by Surgeon-Major Richard Baker, show the extreme frequency with which this condition is met with in India. The cases from which they were taken have been analysed in the columns of THE LANCET. 36 skulls showing the extreme variation in the anatomy of the frontal sinuses in different ages, sexes, and races give the results of an investigation by Dr. Logan Turner. It is surprising what wide variations exist in size, shape, position, and symmetry of these cavities.

BACTERIOLOGY.

Dr. Sims Woodhead, an old Edinburgh student, now director of the conjoint laboratories in London, exhibited specimens illustrating his experimental inoculation of animals with tuberculosis, glanders, plague, anthrax, diphtheria, and pyogenic microbes. He also showed a beautifully prepared educational set of cultures of all the well-known micro-organisms and photographs of the same. Dr. Shennan and Dr. Muir exhibited similar specimens, altogether making a wonderfully complete series. We have mentioned the foregoing only as samples of this museum in its educational and surgical aspects. There are many others to which we would gladly have accorded space had it been possible. The medical and other exhibits will be noticed in a future number.

THE ANNUAL MUSEUM.

(Continued from page 304).

I.—DRUGS—*(Continued).*

SANOSE is the name given to a compound of casein (80 per cent.) and albumose (120 per cent.). It was recently the subject of analytical notice in our columns. There can be little doubt of its high nourishing power. Together with this interesting substance Messrs. A. and M. Zimmerman (9 and 10, St. Mary-at Hill) showed specimens of eucain

Digitized by Google

hydrochloride (Schering), piperazine, urotropine, and Kalle and Co.'s orexin hydrochlor, orexin being a useful stomachic, stimulating the acid secretion and muscular coats of the stomach. Messrs. Alfred Bishop and Sons (48, Spelman-street, Mile End New Town, E.) occupied with their well-known granular effervescent preparations a well-planned stall. The effervescent compressed tablets known as "varalettes" are worthy of mention as presenting in a very convenient form many of the drugs employed in the treatment of gout, such as lithia and piperazine, in an effervescent and agreeable form. There were some very elegant specimens of pharmacy on the tastefully-arranged stall of Mr. John T. Coats (105, 107, Broughton-street, Edinburgh). Amongst these may be mentioned a carefully-prepared petroleum cream with the hypophosphites and glycerites (solutions of medicaments in glycerine), as, for example, hypophosphite of lime in glycerine, iodide of iron, and so on. Novelties might be expected on the stall of the Elberfeld Fabriken Co. (19, St. Dunstan's-hill), and as a matter of fact the following were submitted for inspection: iron-somatose for chlorosis and anæmia, milk-somatose, a compound of albumose with milk proteids, protargol, a silver albumen compound of value in gonorrhœa, and, lastly, iodo-thyrine, the active principle of the thyroid gland. "Sol iodi" was a preparation of interest shown by Messrs. Brooks and Co. (136, Lower Baggot-street, Dublin), which, while not causing irritation or vesication, is freely absorbed by the skin; it has been employed with excellent results, it is said, in the treatment of indurated glands and swollen joints.

II.—FOODS AND FOOD PRODUCTS.

Special foods and food products proved to be an important feature of the exhibition and it was a section which attracted considerable interest. Enormous progress has been made of late years in the preparation of special foods, more particularly of diabetic foods, infant foods, predigested foods, concentrated meat foods, and so on, all of which have a special interest for the medical practitioner. It is remarkable how in regard to taste and appearance certain articles are now made to resemble ordinary food, at the same time providing an article of diet suited to special conditions. For example, the starchless and sugarless foods for the diabetic are now so cleverly prepared as to be hardly distinguishable from the ordinary farinaceous substances. At least, such is the impression gained, for instance, from an inspection of Messrs. Callard and Co.'s exhibit (65, Regent-street, W.). Here was displayed a wonderful variety of foods, bread, biscuits, cakes, savoury sandwiches, all of which by the iodine test showed no starch and yet were palatable and afforded no evidence in regard to taste and appearance that starch and sugar were absent ingredients. Similarly, G. Van Abbott and Sons (6, Duke-street Mansions, Grosvenor-road, W.) had a stall crowded with foods suitable for the diabetic, dyspeptic and invalid. The exhibit included "dietetic bran biscuits," "Kalos" biscuits for obesity, gluten bread, soya flour biscuits and bread, hypophosphite of lime biscuits, digestive biscuits. The collection was simply replete with foods for special purposes. There were some excellent innovations in the same direction in the exhibit of Mr. Robert McVitie (23, 24, and 25, Queensferry-street, Edinburgh). Amongst them may be mentioned peptonised bread, gluten and almond rolls, imitation oatcake containing bran and almond, cocoanut almond, gluten and bran loaves and rolls. A food of undoubted merit is Nutroa food (Nutroa, Ltd., 54, Chiswell-street, E.C.). It contains active diastase, so that in the course of preparation the starch is largely converted into dextrin and maltose. In other respects it presents a well-balanced composition containing fat, carbohydrates and proteids in satisfactory proportions. "Albene" is described as a pure and highly-refined vegetable fat. Examples of its many applications were given at the stall of Messrs. Broomfield and Co. (83, Upper Thames-street, E.C.). It seems an excellent substitute for butter in cookery, it keeps sweet, and is especially good for frying purposes. Albene is used also as an ointment. Close by there were the great number of specialities of the Bovril Company (30, Farringdon-street, E.C.), who were the pioneers in enabling the public to obtain at refreshment bars a good, cheap, and palatable nutrient and stimulant. The exhibit included the special emergency foods similar to those prepared for the Nansen, Jackson-Harmsworth, and similar expeditions. Under the section of foods may be included the excellent malt products of the Distillers' Company, Limited, Edinburgh. As is pointed out the company are large buyers of grain and in the preparation of Malt Extract great care is exercised to employ only the finest barley. Besides the powerfully active Malt Extract they also make a good compound of malt and cod-liver oil. A comparatively new food product is "Protene," of the Protene Company, Ltd. (36, Welbeck-street, Cavendish-square, W.). It is essentially proteid prepared from milk and may be used very profitably for enriching certain foods. Protene is soluble in hot and cold water and is practically tasteless. It contains the mineral salts (chiefly phosphates) of milk. It is a powerful nitrogenous food.

Cocoa was represented by two well-known makers. Messrs. Cadbury Brothers (Bourneville) had a well-arranged stall in which their pure cocoa was displayed in packets and cases and many visitors were glad of the opportunity of partaking of the refreshing and nutritious cup. A special feature of the cocoa of Messrs. Rothwell (Wigan) is the small proportion of indigestible fat which it contains, as we have already pointed out in our analytical columns, while solubility is none the less an important property of this pure preparation. We have already alluded to the fine pharmaceutical preparations of Messrs. Parke, Davis, and Co., (21, North Audley-street, W.), and the exhibit included the food products associated with the name of Mosquera. These are not mere meat extracts but contain the sustaining and nourishing constituents derived from meat as represented in peptone, albumen, and fibrin. The beef jelly contains the fibrin in a peptonised state, effected by the digestive ferment of pineapple juice. It contains also the stimulating extractives of beef. The beef meal (Mosquera) is a predigested powdered meat and is a very highly concentrated and powerful meat food. Analyses have shown the nutritive power of Mosquera's beef preparations. Lipton's fluid beef and extract of beef have so recently been the subject of analysis and report in THE LANCET Laboratory as to need no further comment. The stall was well arranged and the visitors were offered the opportunity of making practical inquiry into the merits of both preparations in a cup of beef-tea or soup. A very useful departure has been made by the Valentine Extract Company, Ltd. (St. George's House, Eastcheap, E.C.) in enclosing meat essence in capsules of various sizes. Consequently upon not carrying the concentration of the extract to excess the flavour is particularly good. The "valtine" globules are very handy for preparing soup or beef-tea. They contain no flavouring materials, these being put up separately in the form of "peloids." Hovis bread is a very good example of the attention which has of late years been directed to this important branch of dietetics. As is well known Hovis flour contains the wheat germ, with the result that it produces a highly nutritive and palatable bread. The stall of the Hovis Company (Hovis Flour Mills, Macclesfield) was an imposing one and in a commanding position. An important food adjunct is Cerebos Salt which is a great improvement on ordinary table salt. It is a fine dry powder enriched with a certain proportion of phosphatic salts. This company (Cerebos, Ltd., Newcastle and London) also exhibited Pepsalia, a refined table salt containing a digestive agent. Messrs. Carnrick & Co. exhibited a fine series of food products, including their liquid and beef peptonoids, the former being also combined with erythroxylon coca. They are each and all excellent nutrients consisting of digested beef, milk, and gluten. The addition of coca-leaf to the preparation contributes, of course, tonic properties. The soluble food for infants is also a very successful preparation, being made from cow's milk, dextrinised wheat flour, and malted barley. The composition of the Allenburys foods for infants (Allen and Hanbury, Plough-court, Lombard-street) is based on a knowledge of physiological requirements, as we have previously shown, and the evidence of experience justifies the claims made in regard to them. They consist of No. 1, No. 2, and No. 3, each adapted to the various stages from birth upwards in infant life. The widely known specialities of Messrs. Brand and Co., Ltd. (11, Little Stanhope-street, Mayfair), were well represented. The beef, mutton, veal, and chicken peptones call especially for notice as admirably adapted to the wants of invalids and others suffering from enfeebled digestive function. Messrs. Fairchild Bros. and Foster (Snow-hill-buildings, E.C.) have long been honourably associated with "digestive products," and quite recently we have placed on record the results of some satisfactory trials

Digitized by Google

which we have made in THE LANCET Laboratory of "panopepton," a predigested beef and wheat preparation, "pepsencia," a clear palatable solution of the active digestive agents of the gastric glands, and "peptogenic milk powder," for the extemporaneous preparation of fresh humanised milk. Besides these there were exhibited pepsin in scales, glycerinum pepticum, and the zymine tabloids and peptonising tubes and trypsin, for the excellence of all of which the firm is well known. Amongst other prepared cereal foods was Mellin's food (Marlborough Works, Stafford-street, Peckham, S.E.), which contains a large proportion of maltose and dextrin as the result of the action of diastase on the cereal grain. When combined with fresh cow's milk the preparation is known as lacto-glycose. In addition to these were Mellin's food biscuits, containing 50 per cent. of the food with wheaten flour; and Mellin's cod-liver oil emulsion free from alkali, and a permanent cream-like emulsion. Concentrated milks were represented at the stall of the Anglo-Swiss Condensed Milk Co. (10, Mark-lane, E.C.), who have done a great deal towards perfecting this product and keeping it up to a satisfactory standard of chemical and physiological composition; and by Henri Nestlé (48, Cannon-street, E.C.), who claims for his Swiss milk that it is the richest in cream. Both sweetened and unsweetened products were shown. Vimbos fluid beef (Vimbos, Ltd., 130, Queen Victoria-street, E.C.) maintains its character and keeps satisfactory pace with its powerful competitors. Its flavour is pleasantly beefy and it serves unquestionably as a powerful meat food. The exhibit included also Vimbos lozenges, which are said to be free from gelatin and contain finely divided muscular fibre. One of the first dry malted milk preparations was Horlick food, which is composed of the soluble portions of wheat and barley combined with fresh cow's milk and evaporated and dried to a crisp mass. The stall of the company (Horlick and Co., 34, Farringdon-road, E.C.) was tastefully arranged. Lastly, meat preparations formed a feature of the exhibit of Messrs. Armour and Co.'s (59, Tooley-street, S.E.), whom we have mentioned in another section in connexion with their preparations of animal substances. The extract of beef is a concentrated preparation, one part representing forty parts by weight of lean beef. It is reduced *in vacuo* by gentle heat. It retains the pleasant beefy flavour of the fresh meat unimpaired. "Vigoral" is prepared in a similar way, but it contains more albuminous constituents as well as the muscular fibre of beef. It is thus a powerfnl nutrient as well as invigorant.

Medical News.

UNIVERSITY OF LONDON.—The following candidates were successful at the intermediate examination in Medicine in July:—

EXAMINATION FOR HONOURS.

Anatomy.—First class: Thomas Copeland Savage (exhibition and a gold medal), University College. Second class: Sidney Herbert Bown, University College. Third class: Walter Fedde Fedden, St. George's Hospital; and Alec Leslie Matthews and Alfred Bertram Soltau, London Hospital.

Physiology and Histology.—First class: Arthur Edmunds, B.Sc. (exhibition and a gold medal), King's College; and William Henry Wynn, B.Sc. (gold medal), Mason University College. Second class: Julius Meyer Bernstein, Owens College; Arthur Eastwood, Cambridge University and Owens College; and Alfred Bertram Soltau, London Hospital. Third class: William Osborne Greenwood, Yorkshire College; and Stanley Hodgson, Guy's Hospital.

Organic Chemistry.—Second class: Howard Welles Reynolds, University College.

Materia Medica and Pharmaceutical Chemistry.—First class: Arthur Eastwood (exhibition and gold medal), Cambridge University and Owens College; Arthur Edmunds, King's College; and Oskar Cameron Gruner, Owens College. Second class: Jas. Fredk. Edmund Bridger and Arthur Falconer Hayden, St. Mary's Hospital; William Payne, Westminster Hospital; and Alfred Bertram Soltau, London Hospital. Third class: Thos. Henry Bourne Dobson, Owens College; and Friedrich Grönc, St. Bartholomew's Hospital.

PASS LIST.

Entire Examination.

First Division.—Hermann Balean, London Hospital; Frederick Charles Carlé, King's College; and Florence Elizabeth Willey, B.Sc., London School of Medicine for Women.

Second Division.—Samuel Herbert Lee Abbott, Oxford University; Ernest Gilbert Bark, Mason University College; Felix Anthony Boissière, King's College; Sidney Bree, University College; Charles Hildred Brodribb, St. Mary's Hospital; Amy Jane Burgess, London School of Medicine for Women; William James Butcher, Owens College; Frank Challans, London Hospital; Katherine Chamberlain, London School of Medicine and Royal Free Hospital; Geoffrey Clarke, Owens College; Ernest Langsford Clay, Mason University College; Alfred Coleridge, University College, Bristol; Hector Alfred Colwell, St. Bartholomew's Hospital; Walter Robert Dunstan, London Hospital; Benjamin Gregory Fiddian, University College, Cardiff; Frederick Goulburn Gibson, Guy's Hospital; Joseph Strickland Goodall, Middlesex Hospital; Herbert Hallilay, Westminster Hospital; John Abbott B. Hammond, Guy's Hospital; Charles Dainty Hatrick and Lionel Gordon Hopkins, University College; John Frederick Jennings and Alfred Ernest Jones, University College, Cardiff; Helena Gertrude Jones, London School of Medicine and Royal Free Hospital; Ernest William Julius Ladell and Edward Vaughan Lindsey, St. Bartholomew's Hospital; John Wishart Little, St. Thomas's Hospital; John Allden Lloyd, St. Bartholomew's Hospital; Charles Alfred March, London Hospital; Zebulon Mennell and Robert Ellis Roberts, B.Sc., St. Thomas's Hospital; Ellen Mary Sharp, London School of Medicine and Royal Free Hospital; Charles Cecil Connock Shaw, St. Mary's Hospital; Harold Weightman Sinclair and Hugh Stannus Stannus, St. Thomas's Hospital; Claude Tessier, Guy's Hospital; Arthur Hitchings Thomas, University College, Cardiff; Kenneth Vincent Trubshaw, Guy's Hospital; Herbert Septimus Ward, University College, Cardiff; Frederick Norman White, St. Bartholomew's Hospital; Alfred Carleton Williams, King's College; Arthur Gordon Wilson, Owens College and Manchester Royal Infirmary; and Edith Louisa Young, London School of Medicine and Royal Free Hospital.

Excluding Physiology.

Second Division.—Edward Walter Bain, London Hospital; Robert Macpherson Barron and Frederick Alexander Beattie, Guy's Hospital; Francis Joseph Birks, University College, Sheffield; John Dell Bridger, Guy's Hospital; Adrian Caddy, St. George's Hospital; Norman Carpmael, St. Thomas's Hospital; David Ellis, London Hospital; David Forsyth, Guy's Hospital; Sydney Balch Green, St. Bartholomew's Hospital; Arthur Charles Haslam, St. Thomas's Hospital; Robert Archer Lloyd and Ernest Charles Mackay, St. Bartholomew's Hospital; Thomas Arnold Matthews, Sidney James Ormond, Alan Carpmael Ransford, and Morgan James Rees, Guy's Hospital; Charles Haldane Denny Robbs and James John Sheat Scrase, St. Bartholomew's Hospital; Douglas Wilberforce Smith, Edinburgh University and School of Medicine; James Henry Stormont, Mason College; and Arthur Stanley Woodwark, St. Bartholomew's Hospital.

Physiology only.

Second Division.—Noel Charles Beaumont, St. Bartholomew's Hospital; Anthony Birch, St. Mary's Hospital; Robert Harrison Birtwell, B.A., London Hospital; Allen Bathurst Brown, St. Bartholomew's Hospital; William Collings Dawson, Mason University College; Alice Debenham, London School of Medicine for Women; Edward Percy Hughes Dudley, St. Bartholomew's Hospital; Alexander Fraser, Guy's Hospital; David Thomas Cadvan Jones, University College; Ernest Williams Jones, Mason University College; Elizabeth Knight, London School of Medicine for Women; John Tyley M. McDougall, Arthur Moon, and Daniel Leigh Morgan, Guy's Hospital; Eugene Michael Niall and Thomas Massey Pearce, St. Bartholomew's Hospital; Mary Elizabeth Phillips, University College, Cardiff, and Royal Free Hospital; Mary Ariel Stewart, London School of Medicine for Women; Ernest Wethered, St. Bartholomew's Hospital; Percy Walter White, Bristol Medical School; and Gisela Wilmersdoerffer, London School of Medicine for Women.

THE VICTORIA UNIVERSITY.—In July the following candidates were successful in the subjects indicated:—

FACULTY OF MEDICINE.

First Examination.

Part II. Biology.—J. W. Anderton and J. H. Bateson, Owens College; J. P. Bligh, University College; L. R. Braithwaite, Yorkshire College; Walter Briggs, C. H. Bromhall, and G. H. Brown, Owens College; Stanley Brown, University College; Thomas Brown, Yorkshire College; John Brunskill, Owens College; Alexander Burkhard and L. T. Chadwick, Yorkshire College; A. G. Christian and W. E. Cooke, University College; E. H. Cox, Owens College; E. H. Crawley, Yorkshire College; J. A. Davenport and A. J. Edmunds, Owens College; Douglas Elder, University College; A. H. Gregson, Owens College; H. E. Heapy, University College; E. W. Henstock, Benjamin Herald, G. R. Hitchin, C. H. Hopwood, Arthur Howard, Ernest Hulme, J. R. Hutchinson, Hamilton Irving, and A. E. Johnson, Owens College; J. A. Johnson, University College; J. A. Jones, Owens College; G. W. N. Joseph and R. E. Knowles, University College; F. H. Lacey, Owens College; R. G. M. Ladell, Yorkshire College; A. W. Latham, Owens College; George Laurence, University College; G. H. Leigh, Owens College; J. T. Lloyd, University College; J. A. Longley, Yorkshire College; Joseph Longworth and T. H. Lund, Owens College; J. F. McCann, University College; Harry Maffin, Yorkshire College; H. E. Moore and J. H. Nichol, Owens College; A. H. Radcliffe, Yorkshire College; W. E. Rothwell, J. A. C. Roy, S. H. Ryan, and F. W. Schofield, Owens College; J. O. Sergeant, Yorkshire College; J. M. Skinner, Owens College; P. K. Steele, Frank Sugden, and Bertram Suggit, Yorkshire College; A. F. Thompson and Leonard Thorp, Owens College; A. B. S. Todd, Yorkshire College; A. E. Townley, F. E. Tylecote, and David Walker, Owens College; G. F. C. Walker, University College; S. A. Winstanley and T. B. Wolstenholme, Owens College; H. F. Woolfenden, University College; and W. S. Wrigley, Owens College.

Second Examination.

A. Anatomy and Physiology.—M. B. Arnold, Owens College; J. H. Billing, C. W. Budden, and Robert Burnet, University College; Daniel Cowin, C. W. Crawshaw, R. F. Ferris, and F. H. Flack, Owens College; A. H. B. Fletcher and R. T. Forster, Yorkshire College; Walter Garstang, W. D. Hamer, E. C. Hulme, and W. C. Johnson, Owens College; R. J. Jones, University College; H. S. Lister and William Parker, Owens College; Percival Pollard,

Digitized by Google

Yorkshire College; Albert Ramsbottom, Owens College; E. C. Roberts and E. E. Roberts, University College; C. W. S. Saberton, W. R. N. Smithard, J. H. Stephens, and George Taylor, Owens College; Ernest Tinker, Yorkshire College; George Unsworth, J. W. Watson, and H. W. Whiteley, Owens College; S. C. Wilkinson, Yorkshire College; and H. M. Williamson, Owens College.

B. Materia Medica and Pharmacy.—John Acomb, Yorkshire College; D. M. Alexander, University College; F. H. S. Ashworth, Owens College; H. M. Berry and J. H. Billing, University College; G. G. Buckley, Owens College; R. N. Butterworth and W. H. Canter, Yorkshire College; J. B. Cook, J. F. Corson, W. J. Cox, and E. N. Cunliffe, Owens College; S. W. Davies, University College; Tom Eastham, D. J. Ferris, R. B. Fletcher, J. E. Floyd, and F. W. Gatenby, Owens College; G. W. Gelderd and V. J. Glover, University College; P. H. Green, Godfrey Heathcote, Rowland Heathcote, James Hindshaw, and W. S. Holmes, Owens College; A. R. Jackson, University College; S. J. C. Johnson, Owens College; C. O. Jones and W. G. Lloyd, University College; W. L. Maccormac, Yorkshire College; Charles Mackey, Owens College; A. F. Martin, C. T. Matthews, and R. V. A. Mosley, Yorkshire College; J. S. W. Nuttall, University College; T. F. Okell, Owens College; W. V. Pegler and Sydney Platts, Yorkshire College; H. H. Rayner and Arthur Richmond, Owens College; Edwin Saville, Yorkshire College; F. R. Sawdon, G. H. Shaw, W. R. N. Smithard, and H. G. Tansley, Owens College; J. C. Teasdale and Ernest Tinker, Yorkshire College; and H. C. Waterhouse, Alwyn Wharton, B. M. Wilson, and J. G. Woolham, Owens College.

Final Examination.

Part I.—G. P. Alderson, University College; T. P. Allen, Owens College; W. J. W. Anderson and J. D. Andrews, Yorkshire College; H. N. Bridge and J. P. Brown, Owens College; P. A. Browne and J. S. Byrne, University College; H. H. Bywater, A. H. Capamagian, Walter Crabtree, and C. H. Dawson, Owens College; R. J. Ewart, University College; E. W. Falconer, Owens College; C. H. Ferguson and H. M. Fletcher, University College; Charles Garner and Archer Greenwood, Owens College; C. H. Greenwood and H. C. R. Hime, Yorkshire College; J. C. Hindley, Owens College; J. A. Howard, University College; W. A. Illingworth, Hugh Lett, and E. O. Libbey, Yorkshire College; C. J. N. Longridge, Owens College; J. W. Miller, University College; Joseph Moreton and F. A. Morrison, Owens College; Armitage Morton, Yorkshire College; A. H. Priestley, A. E. Rayner, and T. E. Regan, Owens College; J. E. H. Scott, Yorkshire College; Harry Scholefield, C. E. Silvester, and Harold Snape, Owens College; T. J. Thomas and Harry West, University College; and A. G. Wilkins and J. D. Windle, Owens College.

Part II.—D. A. Alexander and J. W. Anderson, University College; Godfrey Carter, Harry Dunk, and Arthur Firth, Yorkshire College; †E. W. Floyd and J. P. H. Greenhalgh, Owens College; H. F. Hart, University College; E. M. Hime, Yorkshire College; Frederic Hoyle, Owens College; F. W. Inman, University College; Alfred Lomas and H. H. McNabb, Owens College; W. F. Oyston, Yorkshire College; Stanley Pickering, William Sankey, and A. T. Sissons, Owens College; †Ambrose Spong, Harry Stansfield, *Edward Trotter, and †Edward Turton, Yorkshire College; G. C. Walker, University College; T. H. Wignall, Owens College; Joshua Williamson, Yorkshire College; and J. D. Windle, Owens College.

* Awarded first-class honours. † Awarded second-class honours.

FACULTY OF SCIENCE.

Intermediate Examination.—F. W. Hunt, Yorks; and Arthur Law and Maude E. Young, University College.

Diploma in Public Health.—A. E. Brindley, David Ligat, R. W. Marsden, G. E. Scholefield, and H. A. Scott.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

—At the July conjoint examinations of the three Scottish medical colleges held in Glasgow the following candidates passed the respective examinations:—

First Examination, Four Years' Course.—Angus Macleod, Stornoway; Thomas Taylor Smith, Halifax; Ernest James Nichols, Northamptonshire; and John Lindsay, Edinburgh.

First Examination, Five Years' Course.—Donald Grant Dingwall, Aultbea, Ross-shire (with distinction); John O'Regan, Mitchelstown; William Bates, Partick; Harry Anderson Lunn, Jedburgh (with distinction); Walter Paton Scott, Glasgow; James Henderson Milne, Glasgow; Andrew Young, Langholm (with distinction); George Logan Clark, Glasgow (with distinction); Robert John Roberts, Bala; Richard Augustine Hegarty, Kinsale; Timothy Foley, Killeagh, co. Cork; Stanley Lister George Donald Maclaine, Mountainash, Glamorgan; David Roberts Williams, Borth, Portmadoc; and Thomas Ernest Harty, Cork.

Second Examination, Four Years' Course.—John Francis Dwyer, Cork; Charles Spencer Buck, London; John Wiglesworth, Liverpool; James Herbert Spray, Leeds; Nelson Johnstone, Dunmanway; Joseph Vincent Usher Somers, Tipperary; and Thomas Alexander Chalmers, Ayrshire.

Second Examination, Five Years' Course.—Albert Edward Ward, Partick; George Kee, Greenock; George Johnstone Campbell, Greenock; Frank Hannah, Lancashire; Geo. Russell Jarvie, Cambuslang (with distinction); Robert Wardlaw, Crofthead; John Allan, Glasgow; Henry Ayrton Chaplin, London; Donald Duff, Glasgow (with distinction); Archibald Macqueen, North Wales; William Hendry Ferguson, Yorkshire; Eyre William Powell, Mount Prospect; John Thomson Malloch, Glasgow; Charlotte M'Crea, Glasgow; Ernest George Dryden Benson, Durham; Harold Ruby Parkinson, Manchester; Jane Mary Louisa Foley, County Cork; and Daniel Michael Donovan, Cork.

Third Examination.—Rupert Edward Moorhead, Mauritius; Thomas Blane Adam, Glasgow; Robert Elwell Naish, Devonport; George Brownlie M'Kendrick, Wishaw; Evelyn John Evatt, Liverpool; John Thomas Bradley, County Clare; Thomas Stratford Logan, Yorkshire; Frederick William Newcombe, Victoria, Australia; William Patullo, Alyth; Timothy Joseph O'Donovan, Dunmanway; John George Grant, London; and Richard Nason Woodley, County Cork.

Final Examination (and admitted Licentiates).—David Campbell, Taynuilt; Arthur Bulleid, Glastonbury; John Glen Parker, Meiklerigg, Paisley; Thomas Buchanan Whitelaw, Glasgow; Samuel Vernon Robinson, Ulverston; Reginald Storrs, Doncaster; Richard Maddern Powell, Liverpool; John Dick, Greenock; John Joseph Aloysius Sherry, Dublin; Harold Chaffer, Todmorden; David Richard Edwards, South Wales; Henry Arthur Marquis, Padiham; William Arthur Clayton, Manchester; Henry Stewart Anderson, Dunmurry, County Antrim; Claud Herbert Lucien Bellot, Edinburgh; Dewan Gaupat Rai, Edinburgh; Benjamin Samuel Reyhardt, Ceylon; and Peter Aitken, Glasgow.

BRUSSELS UNIVERSITY.

—The following British practitioners obtained the M.D. degree at the June examination, viz.:—

E. S. Bell, A. D. Cowburn, C. J. Glasson (Honours), J. S. Hudson, C. Lamplough, W. McCall, J. Persehouse, W. Reeve, and Spencer Cox.

FOREIGN UNIVERSITY INTELLIGENCE.

—*Barcelona:* Dr. Francisco Millán y Guillén has been appointed to the chair of Anatomy and Embryology.—*Berlin:* Dr. Friedrich Kopsch has been recognised as *privat-docent* of Anatomy and Dr. Hugo Michaelis and Dr. Wilhelm Zinn as *privat-docenten* of Internal Medicine.—*Budapest:* Dr. Paul Kuzmik has been recognised as *privat-docent* of Surgery.—*Erlangen:* Dr. Richard Fleischer, Extraordinary Professor of Internal Medicine, has been appointed to the chair of Medical Propædeutics and the History of Medicine. Dr. Ludwig Heim, Extraordinary Professor, has been appointed Director of the Institute of Hygiene and Bacteriology.—*Giessen:* Dr. Hans Köppe has been recognised as *privat-docent* of Physiology.—*Innsbruck:* Dr. Ludwig Kerschner, Extraordinary Professor of Histology and Embryology, has been promoted to be Ordinary Professor.—*Leipsic:* Dr. Otto Schwarz, *privat-docent* of Ophthalmology, has been promoted to be Extraordinary Professor.—*Munich:* Dr. Philipp Schech, Extraordinary Professor of Internal Medicine, is giving up his lectures on Balneo-therapeutics and Climatology and will devote himself to Laryngology. Practical instruction in hydro-therapeutics, electro-therapeutics, and other mechanical methods of dealing with disease will be given by Dr. Hermann Rieder, who has been appointed to an Extraordinary Professorship.—*Naples:* Dr. Carlo Gangitano has been recognised as *privat-docent* of Operative Medicine.—*Prague (German University):* Dr. Ludwig Waelsch has been recognised as *privat-docent* of Dermatology and Syphilis, and Dr. A. Velich as *privat-docent* of General and Experimental Pathology.

PRESENTATIONS TO MEDICAL MEN.

—The members of the Ilfracombe Choral Society have presented Mr. John Twiname Gardner, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., with a 70-guinea grandfather's clock in recognition of his services as honorary conductor. The presentation was made by Mrs. Bassett of Watermouth Castle in the presence of a large gathering of ladies and gentlemen.—On July 12th Sir James Laing, in the lecture hall of the Sunderland Infirmary, presented to Mr. G. B. Morgan, L.R.C.S. Irel., L.S.A., the senior surgeon of the institution, a testimonial consisting of his portrait, a brass tablet to be placed in the Morgan Ward, a silver bowl, a silver candelabrum, silver candlesticks, and a silver tray. These presents were subscribed for by the president, vice-presidents, members of the General Committee, and the medical board of the infirmary. Mr. Morgan has been connected with the Sunderland Infirmary for upwards of 40 years and during that long career has done, perhaps, more than any other individual to promote the interests of the charity. Mr. Morgan is not retiring from the staff and it is to be hoped that he may be able to retain his position for many years to come. There is no member of the profession in the neighbourhood more universally respected than Mr. Morgan and no one better deserves the position he enjoys.—The members of the Rotherham Borough Police ambulance class, on the occasion of the distribution of the certificates and medallions for efficiency on July 15th, presented to Mr. F. B. J. Baldwin, M.R.C.S. Eng., of Rotherham, a silver and ebony inkstand as a memento of his appreciated instructions on first aid.—On July 16th at a meeting of the members of the Hull Railway Goods No. 1 Ambulance Class Mr. James Stothard, M.R.C.S. Eng., of Hull, was the recipient of an ivory-handled malacca cane

Digitized by Google

mounted in silver and bearing an inscription, in recognition of his honorary services to the class. — Mr. S. Macaulay, L.R.C.P. Edin., L.F.P.S. Glasg., who has been on the surgical staff of the Newcastle Throat and Ear Hospital for 17 years, has, on the eve of his departure to South-Western Australia, been presented by his colleagues and other officials of the institution with an illuminated address expressive of their esteem. Mrs. Macaulay was at the same time presented with a diamond and ruby ring. — Mr. C. F. France, M.R.C.S. Eng., L.R.C.P. Lond., was the recipient on July 23rd from the members of the Great Central Railway (Wigan Centre) Ambulance Class of a silver-mounted walking-stick as a mark of esteem.— Mr. B. J. Adam, M.B., Ch.M. Glasg., who has practised for the past ten years at Beaufort, Victoria, Australia, has been presented by the inhabitants of the town and district of Beaufort with an illuminated address and a piece of plate on his leaving the locality.—On July 16th Mr. P. B. Stoney, L.R.C.P. Edin., M.R.C.S. Eng., of Millom, Cumberland, was the recipient from the local ambulance class of an umbrella bearing an inscription and a new edition of an important medical work, as tokens of thanks for his first aid ambulance lectures.

VACCINATION GRANT.—Mr. George Stevens, of Norton, Bury St. Edmunds, public vaccinator of the Stow Union, has been awarded the Government grant for efficient vaccination for the tenth time in succession.

THE DISAPPOINTMENTS OF A WORKHOUSE NURSE. —At the meeting of the Keynsham board of guardians held on July 26th the chairman announced that the candidate whom they wished to appoint as nurse to the workhouse had withdrawn her application as there was no sea view at Keynsham. She was also disappointed because there was no tennis court for her use. Some considerable discussion took place upon the bill for travelling expenses which the candidate had incurred, but the guardians eventually decided to allow them.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.— The deaths of the following eminent foreign medical men are announced:—Dr. Wilhelm Lohmann, one of the representative members of the Hanover Medical Council, at the age of sixty-three years. His views on medical politics were what is called Liberal, as he was opposed to all measures directed against quackery.—Dr. Alfred Obalinski, Professor of Surgery in the University of Cracow, at the age of fifty-five years. He was a voluminous writer on many subjects of a surgical character and was recognised as one of the first of Polish surgeons.—Dr. Dufay, formerly Senator for Loir-et-Cher.— Dr. Resario Pugliatti, Extraordinary Professor of Midwifery and Gynæcology in the Messina Medical School.—Dr. Carlo Giacomini, Professor of Anatomy in the University of Turin.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Food Products Adulteration.

THE Bill on this subject introduced in the House of Commons by Mr CHAPLIN was withdrawn on Thursday, July 28th, without any attempt being made in the House to read it a second time.

Vaccination Bill.

The House of Lords received the Vaccination Bill from the Commons on Monday, Aug. 1st and at once read it a first time, and on Tuesday, Aug. 2nd, after a short speech from Lord HARRIS, read it a second time, fixing the committee stage for Thursday, Aug. 4th.

HOUSE OF COMMONS.

THURSDAY, JULY 28TH.

Experiments on Living Animals.

Mr. SAMUEL SMITH asked the President of the Board of Agriculture whether he had consented to a vivisectional laboratory being attached to the Department of the Board of Agriculture at which experiments may be made on horses, dogs, and other highly organised animals; and whether such experiments were allowed there without the use of anæsthetics.—Mr. LONG replied: Our veterinary officers are at present engaged in an investigation into the curative and other properties of mallein, and they have also to diagnose suspected cases of rabies. For these purposes inoculation is requisite and the officers in question have therefore obtained certificates under the Act of 1876. There has been no new departure in this respect, it having been customary for many years past for my veterinary advisers to obtain such certificates for investigations connected with the suppression of contagious diseases amongst animals. Anæsthetics are employed in connexion with the work under the second head above referred to, but not in cases under the first head. No experiments have at any time been made by my officers upon dogs.

Colonel LOCKWOOD raised this question in connexion with the vote for the Home Office on Friday, suggesting that the laboratories where the experiments are carried on should be open to the inspection of University graduates and medical men as representing the public.—Sir MATTHEW WHITE RIDLEY assured the House that the Act is very strictly enforced. He could not admit, however, that University graduates representing the public should have the right to be present whenever an experiment was made. It was provided that the experiments should be real experiments, and should be performed in a proper place, that the experimenters should be recommended by competent scientific men and that a return should be made of what was done. All these requirements were strictly enforced. If the number of experiments had increased in the last few years the increase was due to inoculation experiments. The surgical experiments had very much decreased. He should be ready to meet any reasonable suggestion as to the better working of the Act.

The Vaccination of Pupil Teachers.

Mr. LABOUCHERE asked the Vice-President of the Committee of Council on Education whether it was his intention to maintain in the Education Code the article which requires probationers for pupil teachership to show proof of vaccination before the department assents to their indentures.—Sir JOHN GORST replied that the Committee of Council had no intention of changing the rule which requires pupil teachers to be vaccinated before admission.

Rabies in London

Mr. TRITTON asked the President of the Board of Agriculture if he was now in a position to withdraw the order relating to the muzzling of dogs in the metropolitan area south of the Thames.—Mr. LONG, in reply, said: The fact that an outbreak of rabies occurred at Bow so recently as June 8th last shows, I am afraid, that although the position has so substantially improved, there is still reason to believe that the disease lingers within the metropolitan area. My hon. friend will understand that I am very anxious to avoid the necessity of reimposing any of the muzzling orders now in force when once they have been withdrawn, and under existing circumstances there would be a great danger that this would be the case, so far as South London is concerned.

FRIDAY, JULY 29TH.

Vaccination

Mr. TALBOT asked the President of the Local Government Board whether he would consider the advisability of circulating to the various boards of guardians throughout the country information on the subject of vaccination which might be distributed by them in leaflet form so as to carry out the intention of Parliament to encourage the general use of vaccination though no longer enforced by law.—Mr. CHAPLIN replied that he was quite prepared to consider the proposal, though he must not be understood as giving any pledge on the subject.

Medical Service at the Army Manœuvres.

Captain NORTON asked the Under Secretary of State for War whether he could state the number of field hospitals and bearer companies as well as the number of medical officers and men of the Army Medical Corps required for the forces to be employed at the forthcoming manœuvres.—Mr. BRODRICK replied that there would be 4 field hospitals and 2 bearer companies; 72 officers and 301 men of the Royal Army Medical Corps would be employed at the manœuvres.

Woolsorters' Disease in Bradford

Mr. FORTESCUE FLANNERY asked the Home Secretary whether his attention had been called to recent deaths from woolsorters' disease in Bradford occurring from alleged infection in the carding-room as distinguished from the sorting-room; whether the recently adopted woolsorters' rules had been extended to the carding-room; and whether he could see his way to hold an inquiry, through the factory inspectors or otherwise, as to whether or not the rules should be extended to carding-rooms.—Sir M. WHITE RIDLEY replied: My attention has been called to this matter. The reports I have received showed that in the most recent case, though the man was employed in the card-room it was not from his own work that the infection reached him. The rules do not apply to the process of carding and as they deal with dust as the medium of infection could not be applied *en bloc*. The matter is a serious one and I propose to institute inquiries.

Lead and Phosphorus Poisoning.

In connexion with the vote for the Home Office there was long debate at this sitting on lead-poisoning in the Potteries and "phossy jaw" in the match industry. Speeches were delivered by Mr. Tennant, Sir John Stirling-Maxwell, Sir Charles Dilke, Mr. Asquith, and others calling attention to the state of affairs and inviting action on the part of the Home Office to deal with it.—Sir MATTHEW WHITE RIDLEY, in his reply, explained what has been done by his department, and the inquiries which are being made. He said they were beginning to find out that the special rules are not likely to be sufficient to meet the case, and he intimated that when the proper time arrives he would not be averse to undertaking further legislation. He also expressed his readiness to consider what advantage is likely to accrue from sending a lady inspector to reside and carry on her work in the Potteries district.

SATURDAY, JULY 30TH.

The Vaccination Bill.

The House occupied several hours of this sitting with the consideration of the Vaccination Bill. Members on the Ministerial side of the House put forward a motion for the recommittal of the Bill, mainly on the ground that the question of conscientious objection required reconsideration. The Government met the motion by saying that this subject had been sufficiently discussed and that the House must either accept the Bill as it stood or abandon it altogether. Several members

Digitized by Google

referred to the attitude of the medical profession towards the Bill, and in regard to the declaration of the Royal College of Physicians of London Mr. CHAPLIN said that while he agreed with every word in it he could not help thinking that it would have been a more useful and practical declaration if it had been said whether or no the Royal College agreed with the unanimous recommendation of the Royal Commission for the insertion of a conscience clause. When the issue was brought to a vote only 29 Members voted for recommittal and 133 members voted against it. The motion thus disposed of, the House gave a third reading to the Bill.

MONDAY, AUG. 1ST.

Vaccination Prosecutions in Scotland.

Dr. CLARK asked the Lord Advocate whether his attention had been called to recent vaccination prosecutions at Aberdeen and at Dundee; whether he was aware that in the latter case the sheriff stated that the procedure was oppressive in view of the English legislation which proposed to give relief to persons with conscientious scruples; whether there had been a recent order by the Scottish Local Government Board in favour of more rigorous prosecutions; and whether the majority of the parish council of Abbotshall, in the county of Fife, had resigned in consequence.—The LORD ADVOCATE: My attention has been called to the cases referred to. The case at Dundee was tried before the sheriff substitute, not the sheriff. I have no knowledge of what he said except from the newspaper reports. The answer to the third paragraph of the question is in the negative. On the contrary, I am informed by the Local Government Board for Scotland that they have not departed from the line which they have all along adopted—namely, that parish councils are bound to carry out the existing law. It is the fact that on being called upon to carry out the existing law in regard to first prosecutions, 6 out of 11 of the parish councillors of Abbotshall resigned their seats at the parish council.

TUESDAY, AUGUST 2ND.

Accommodation for Pauper Lunatics in Devon.

Mr. SEALE-HAYNE asked the President of the Local Government Board whether he was aware that for some time past the Devon County Asylum at Exminster has been overcrowded; that the Newton Abbot Board of Guardians has been compelled to send several patients to other asylums, involving a great increase of expense; and that a patient certified by a justice of the peace for removal to an asylum is at the present time unable to be removed as there is no room for her reception either at the Devon County Asylum or other local asylums, or suitable accommodation in the Newton Abbot workhouse. Whether it was true that the Devon County Council are prepared to give increased asylum accommodation, but owing to the great delay which has arisen in consequence of a dispute with the Lunacy Commissioners in regard to the water-supply they had not yet done so; and whether he would take steps to impress upon the authorities the necessity of meeting without further delay the urgent want of increased asylum accommodation for pauper lunatics in the county of Devon.—Sir M. WHITE RIDLEY read this reply, viz.: It is the case that this asylum has for some time past been overcrowded and that on account of difficulties attending the supply of water approval of plans for the enlargement of the asylum was delayed until an adequate and wholesome supply was obtained. These difficulties have now to a great extent been surmounted and I approved in February last of plans of an extension which will provide for additional patients.

Hospital Accommodation at Malta.

Mr. BRODRICK, replying to a question by Dr. Tanner on this subject, said: In view of the increased garrison of Malta the hospital accommodation requires revision and the erection of a new hospital is under consideration. Those hospitals now in use are as sanitary as it is possible to render buildings in Malta which were not built specially for the purpose to which they are now devoted.

Report of the Army Medical Department.

Mr. BRODRICK, in answer to Dr. Tanner, explained that the Report of the Army Medical Department had been presented formally in order to allow its issue during the Parliamentary recess. It would not be ready for publication until late in the year as the returns for India had not yet reached this country.

The Supply of Artificial Limbs in the Navy.

Sir ELLIOTT LEES asked the First Lord of the Admiralty what were the regulations in the service with reference to the supply of artificial limbs to seamen who whilst on duty met with accidents entailing the amputation of a leg or an arm; and whether it would be practicable in all such cases to supply the injured seaman on his discharge from hospital with the best artificial limb procurable free of charge to himself.—Mr. MACARTNEY answered the question in the following terms, viz.: It is the practice to supply in such cases, free of charge to the man, the substitute either for arm or leg which is considered to be most suitable to his requirement. The "best artificial limb procurable" is often an elaborate apparatus which frequently gets out of order and would often not be so useful to the recipient.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ANDERSON, A. R., F.R.C.S. Eng., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Nottingham, Newark, and Bingham, County-court Circuit No. 18.

BARCLAY, J., M.D., C.M. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Banffshire.

BARTLETT, R. C., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health for the Borough of Romsey.

BEATTIE, G. W., M.D., C.M. Aberd., has been re-appointed Medical Officer of Health by the Failsworth Urban District Council.

BENSON, J. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Ashover Sanitary District of the Chesterfield Union.

BENSON, J. R., F.R.C.S. Eng., has been appointed Sambrooke Surgical Registrar and Tutor in Surgery at King's College Hospital, London.

BROWNING, B., L.R.C.P. Lond., M.R.C.S., D.P.H. Edin., has been re-appointed Medical Officer of Health by the Weymouth Urban District Council.

CAMPBELL, J. A., M.D., F.R.S. Edin., has been appointed an Honorary Consulting Physician to the Counties Asylum, Carlisle.

CHADWICK, C. M., M.D. Oxon., F.R.C.P. Lond., M.R.C.S., has been appointed to the Professorship of Materia Medica, Pharmacology, and Therapeutics for the Department of Medicine of the Yorkshire College.

CUFF, A. W., M.B., B.C. Camb., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, to act generally for the Northern Division (Retford, Doncaster, and Thorne), County-court Circuit No. 18, although appointed a Referee for Circuit No. 13.

DARLEY, A. R., M.D., B.Ch. Dubl., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County-court Circuit No. 22 (Rugby Division).

DAUNT, ELLIOT, L.R.C.P. Lond., M.R.C.S., L.S.A. Lond., D.P.H., Conjoint R.C.P. & R.C.S. Dubl., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the Kent District of Circuit No. 48.

FARQUHARSON, W. F., M.D., C.M. Edin., has been promoted to the office of Medical Superintendent of the Counties Asylum, Carlisle.

FINNY, J. M., M.D. Dubl., L.R.C.P., L.R.C.S. Irel., has been appointed to the vacant seat on the Board of Superintendence of the Dublin Hospitals, vice S. Gordon.

GEOGHEGAN, A. V., M.D., B.S. Dubl., has been appointed Medical Officer for the Mickleton Sanitary District of the Shipston-on-Stour Union.

HALL, E. F., M.D. St. And., L.R.C.P. Edin., M.R.C.S., has been appointed a Visiting Physician and Surgeon for the Workhouse of the Prescot Union.

KANDFORD, H., M.D., C.M. Edin., M.R.C.P. Lond., M.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Nottingham, Newark, and Bingham, County-court Circuit No. 18.

HEDGES, C. E., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse and the First Sanitary District of the Newport (Salop) Union.

KENNEDY, A. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Plaistow Sanitary District of the West Ham Union.

KENNEDY, D., L.R.C.P., L.R.C.S. Irel., has been appointed a Visiting Physician to the Waterford County and City Infirmary.

LLOYD, EDWARD J., M.D., Ch.M. Aberd., M.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County-court Circuit No. 29; and to act for the Bangor, Conway, Llandudno, Llangefni, Holyhead, and Menai Bridge County-court Districts.

MCMANUS, GEORGE, L.R.C.P., L.R.C.S. Edin., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for the County of Meath.

MILNE, THOMAS, M.D., C.M. Aberd., has been appointed Medical Examiner for the Iron Trades Employers' Insurance Association for the Aberdeen District.

MILROY, J. A., M.B., C.M. Edin., has been appointed a Demonstrator of Physiology for the Department of Medicine of the Yorkshire College.

OGSTON, ALEX., M.D., C.M. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Aberdeenshire.

O'MEARA, T. J., M.B., C.Ch. Irel., has been appointed Medical Officer for the Dispensary District of Tullagh, in the Skibbereen Union.

PYE-SMITH, R. J., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, to act generally for the Northern Division (Retford, Doncaster, and Thorne), County-court Circuit No. 18, although appointed a Referee for the Circuit No. 13.

PHILLIPS, HUGH R., M.B., Ch.B. Edin., has been appointed Assistant House Surgeon to the County Hospital, York, vice R. H. Ashwin, resigned.

PITT-TAYLOR, F. S., M.B., B.Ch. Vict., has been appointed House Surgeon to the Birkenhead and Wirrall Children's Hospital.

SNELL, S., F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Retford, Doncaster, and Thorne County-court Circuit No. 18, *pro tem.*, and for ophthalmic cases only.

TAYLOR, JAMES, M.D., C.M. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Banffshire.

THRESH, J. C., D.Sc. Lond., M.D. Vict., D.P.H. Camb., has been appointed Lecturer on Public Health at the London Hospital Medical College.

TRIBE, P. C. E., M.B. Lond., L.R.C.P., has been appointed Sambrooke Medical Registrar and Tutor in Medicine at King's College Hospital, London.

WHITE, C. P., M.B., B.C. Camb., F.R.C.S. Eng., L.R.C.P. Lond., M.R.C.S., has been appointed a Demonstrator of Pathology for the Department of Medicine of the Yorkshire College.

WHITE, V., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Holy Ghost Hospital, Waterford, vice T. J. Tobin.

WILL, J. C. O., M.D., C.M. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Kincardineshire.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

BETHLEM ROYAL HOSPITAL, Lambeth-road, London.—Second Assistant Medical Officer. Salary £130 per annum, apartments in the hospital, complete board, and washing being provided. Applications to the Clerk, Bridewell Hospital, New Bridge-street, E.C.

BOROUGH OF DERBY.—Medical Officer of Health. Salary £500 per annum, increasing by £50 per annum to £600 at intervals of two years. Applications to the Town Clerk, Town Hall, Derby.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £70, with board, residence, and washing.

BRADFORD ROYAL INFIRMARY.—Honorary Physician.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE, Chelsea, S.W.—A Teacher of Hygiene.

CARNARVONSHIRE AND ANGLESEY INFIRMARY AND DISPENSARY, Bangor. House Surgeon. Salary £70 per annum, with board and lodging in the house.

CUMBERLAND AND WESTMORELAND ASYLUM, Carlisle.—Senior Assistant Medical Officer. Salary £120 a year, with board. Applications to Dr. Farquharson, Garlands, Carlisle.

DERBY COUNTY ASYLUM, Derby.—Second Assistant Medical Officer, unmarried. Salary £100 per annum, rising to £120, with board, lodging, and washing.

DEVONSHIRE HOSPITAL, Buxton.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E. — Unqualified Clinical Clerkships, tenable for three months.

HUDDERSFIELD INFIRMARY.—Senior Assistant House Surgeon. Salary £50 per annum, with board, residence, and washing. Also Junior Assistant House Surgeon. Salary £40 per annum, with board, residence, and washing.

KING'S COLLEGE HOSPITAL, London.—Assistant Physician.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Resident Medical Officer for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

OWENS COLLEGE, Manchester.—A Senior and Junior Demonstrator in Physiology. Stipends £150, rising to £200, and £100, rising to £150, respectively.

Digitized by Google

PARISH COUNCIL OF EVIE AND RENDALL.—Medical Officer. Salary £45 a year and a free house. Apply to the Inspector of Poor, Evie.

PARISH OF FULHAM.—Public Analyst. Salary £200 per annum. Applications to the Clerk to the Vestry, Town Hall, Walham-green, S.W.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Board, lodging, and washing.

RURAL DISTRICT COUNCIL OF CHESTERFIELD.—Medical Officer of Health for one year. Salary at the rate of £500 per annum, which includes all expenses, stationery excepted. Travelling expenses outside the district will be allowed. Applications to the Clerk to the Council, Union Offices, Chesterfield.

ST. ANN'S HILL HYDROPATHIC ESTABLISHMENT, County of Cork, Ireland.—Resident Medical Superintendent, married.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary £50 per annum, with board and residence.

SOMERSET AND BATH ASYLUM, Wells, Somerset.—Junior Assistant Medical Officer, unmarried. Salary £110, rising to £130, with board, lodging, washing, and attendance.

STOCKTON AND THORNABY HOSPITAL, Stockton-on-Tees. — House Surgeon, non-resident. Salary £200 per annum.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Assistant House Surgeon for six months. Board, washing, and lodging in the hospital provided.

UNIVERSITY COLLEGE, Bristol, Faculty of Medicine.—Demonstratorship of Physiology. Stipend £125.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Medical Officer to the Provident Dispensary attached to the hospital. Salary £80 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

COMBE.—On July 30th, at Brockley-road, S.E., the wife of Charles E. Combe, L.D.S., of a daughter.

HEWLETT.—On July 18th, at Rosebery-villas, Southfields, S.W., the wife of Richard T. Hewlett, M.D., M.R.C.P., of a son.

LEFTWICH.—On July 30th, at Kennington-park-road, the wife of Ralph W. Leftwich, M.D., of a daughter.

MINTER.—On Aug. 2nd, at Sussex Lodge, Uxbridge, the wife of L. J Minter, M.D., M.R.C.S., of a son.

ORMEROD.—On July 30th, at Liphook, Hants, the wife of Charles E. Ormerod, M.D., of a daughter.

RENTZSCH.—On July 29th, at The Firs, Waltham Cross, Herts, the wife of Sigismund H. Rentzsch, of a daughter.

SMITH.—On Aug. 2nd, at Hillbank, Monifieth, Forfarshire, the wife of R. Sinclair Smith, L.R.C.P., L.R.C.S. Edin., of a son.

SUMPTER.—On July 26th, at Denton Hall, Northumberland, the wife of W. J. Ernely Sumpter, L.R.C.P. Lond., M.R.C.S., of Sheringham, Norfolk, of a son.

MARRIAGES.

COCK—EVANS.—On July 27th, at St. Stephen's, Westbourne-park, W., Frederick William Cock, M.D., son of the late Frederick Cock, M.D., to Frances Louisa Evans of 83, Inverness-terrace, Hyde-park.

HEMSTED—MUNN.—On July 28th, at St. Mary's, Laverstoke, Hants, Rustat Henry Hemsted, M.R.C.S., L.R.C.P. Lond., eldest son of Henry Hemsted of Haverhill, Whitchurch, Hants, to Gertrude Mary (Meemee), daughter of Winchester Munn.

SETON-ORR—FLOWER.—On Aug. 3rd, at St. Peter's Church, Cranley-gardens, A. B. Seton-Orr, M.D., of 37, Alfred-place West, South Kensington, to Henrietta Laura Owen (Lollie), daughter of Major Lamorock Flower of Cornwall-mansions, Queen's-gate.

WHITE—WYMAN.—On July 28th, at St. John's Church, Putney, by the Rev. J. White Horne, assisted by the Hon. and Rev. R. Henley, Edwin Francis White, F.R.C.S., of Westlands, Putney, only son of the late Edwin White and grandson of the late Samuel White White of Charlton Marshall, Dorset, and Farnecombe, Surrey, to Mabel, only daughter of Dr. and Mrs. Wyman of Putney. At home Sept. 12th to 14th.

DEATHS.

BEATSON.—On July 29th, at Cromwell-road, Earl's-court, Surgeon-General John Fullarton Beatson, M.D., C.I.E., aged 81 years.

MURRAY.—On July 27th, at Claughbane, Sheringham, John Murray, M.D., Surgeon-General, aged 88.

PECK.—On July 28th, at Malta, William Godfrey Peck, Surgeon R.N. (H.M.S. *Anson*).

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

A FAMOUS CENTENARIAN PHYSICIAN.

ACCORDING to *Le Temps*, Dr. Mavrogenis, the last survivor of the Grecian War of Independence, has just completed his 100th year. Born at Paris in 1798 he prosecuted his medical studies at an Italian university, but in 1821, before his education was quite complete, he returned to his native country, where he greatly distinguished himself in several battles. The numerous wounds he then received have not, however, prevented him from attaining to centennial honours, and he is said to be at the present time in the enjoyment of robust health. Dr. Mavrogenis comes of a family famous for longevity and a sister who is ten years his senior lives with him.

"MR. MOULD FAILS TO FIND MR. JOBLING."

To the Editors of THE LANCET.

SIRS,—There seems to be no limit to the audacity of advertisement nowadays. Some time ago a patient of mine stopped me in the street. "Doctor," she said, "as you always do your posting with our people perhaps you would do us a further favour? Just let your patients know, *when you think you can*, that my husband has invested in a beautiful brand new glass hearse. It looks much neater than the other people's old black one, and we can do it cheaper, too!" This was said quite in the way that a business person discusses business and I am sure was not meant as an insult. I think some of these things are said to us members of the profession because our suasive powers are regarded with high esteem. Gruesome as the subject seems, a moment's reflection will convince one that there is more of a normal and healthy tone in the above than in that of the carneying insurance agent who comes with an idea of getting the doctor's help in "getting through" a proposal on "the life of another," and asks him to "let the case through as easy as you can," when some servant girl is going to speculate 1s. a week on somebody else who "doesn't know nothing about it"—a procedure that such insurance offices openly encourage!

I am, Sirs, your faithfully,

July 27th, 1898. VERITAS.

TUMOURS CAUSED BY PATHOGENIC YEASTS.

AT a meeting of the Greifswald Medical Society, reported in the *Deutsche Medicinische Wochenschrift* of July 21st, Dr. Busse said that although pathogenic yeasts have only been known since the year 1894 a great number of pathogenic species of blastomycetes have been recognised. Their behaviour in the animal body is very interesting, for the naked forms then become surrounded with a capsule which often shows concentric layers. This capsule is very characteristic and gives to the blastomycetes a great similarity to many of the forms which have been described and figured as aggregations of cells enclosed in tumours, and have been regarded as parasites and as the exciting causes of the tumours. There is, in fact, a certain amount of excuse for regarding the yeasts as the causes of the tumours, for when they make their way into the animal body they actually do produce formations resembling tumours. Both at the place of the injection and also in remote organs there occur in the course of weeks or months proliferations which have a glassy-white appearance like myxosarcoma, are very soft, and may ulcerate. Under the microscope, however, the seeming tumours do not present the characteristics of any of the recognised varieties of tumours but are found to be giant colonies of saccharomycetes in the animal organism. Giant cells have appeared in the lungs in great numbers. It is certain, however, that sarcoma has not yet been artificially produced by means of blastomycetes, although it is not impossible that if the virulence of the yeasts could be increased formations might be obtained resembling sarcoma.

MEDICAL ETHICS.

THE *Australasian Medical Gazette* of June 6th reproduces the appended advertisement which appeared in a lay Australian paper: "Dr. A. Crosbie Dixey, Member Royal College Physicians, Edinburgh, wishes to announce he has started a Consulting Practice in New Norfolk. Specialities—Typhoid and other Fevers, and Diseases of Women and Children. 'Woodbridge,' New Norfolk." The Royal College of Physicians of Edinburgh would probably remonstrate with Mr. Dixey if the matter were brought officially to their knowledge.

"THE ARTHUR JEFFARES BARLOW FUND."

To the Editors of THE LANCET.

SIRS,—Kindly acknowledge in your next issue the following subscription to the fund for the widow of the late Mr. Barlow: Dr. W. Alex. Hearnden, £1 1s.

I am, Sirs, yours faithfully,

619, Holloway-road, Aug. 2nd, 1898. J. AGAR MATSON, M.D. Dub.

POISONOUS MUSTARD.

PROFESSOR CARLES, of Bordeaux, draws attention to the dangerous character of mustard as manufactured nowadays for wholesale consumption. Formerly, he says, our fathers used to prepare the condiment for themselves, making use exclusively of fine mustard flour and grape must, but gradually the process became more and more complicated and less wholesome. The first downward step was the utilisation of mustard-seed from which the oil had been extracted, but *factitis descensus Averni*, and eventually "mustard came to be manufactured without any mustard flour at all, its place being taken by any ordinary leguminous flour flavoured with pepper, allspice, ginger, and other pungent matters. Mustard, as manufactured at present in France, is usually sold in jars closely corked by the aid of machinery and further protected by means of a metallic capsule which for the most part is highly plumbiferous. As long as the jar remains unopened the contents do not sensibly deteriorate, but once the cork has been extracted a distinct source of danger arises. The cork having been originally inserted under pressure is difficult to replace and, generally speaking, the housewife discards it, contenting herself with the protection afforded by the capsule. The latter thus directly exposed to the acetic vapour quickly grows oxidised, a more or less basic acetate, amorphous or crystalline, being formed which adheres so loosely to the metal that at the slightest shake it falls back into the jar. The acetate of lead is white and sweetish, so there is nothing to draw the consumer's attention to its noxious character. He swallows it heedlessly and should he be a habitual mustard-eater runs a considerable risk of lead poisoning. Professor Carles's advice in conclusion to all mustard-eaters is to reject the brands the capsules of which become lined either with minute crystals or with a white powder.

FORBEARANCE RECOMMENDED.

To the Editors of THE LANCET.

SIRS,—I should very much like your opinion on the ethics of the enclosed letter which was written to the board under which I hold the parish appointment. The facts of the case are shortly these: A man was attended by Mr. ——. The man then got a parish order and sent for me. I went and saw him and recommended removal to a hospital and said that I would treat him till the removal was arranged. They never fetched the medicine and they never sent me any word whether he had gone to the hospital or whether he was better or worse. The next thing I heard about the case was when the letter enclosed was sent me. Of course I did not visit him a second time as they had not sent for any medicine, or requested me to do so.

I am, Sirs, yours faithfully,

July 30th, 1898. THE POOR LAW MEDICAL OFFICER.

[ENCLOSURE.]

The Chairman of Board of Guardians ——. July 5th, 1898.

DEAR SIR,—I wish to move a complaint respecting —— —— of ——. A fortnight ago the medical officer for the parish saw —— —— and has not seen him since. The man is in a serious condition. It was a hospital case and the man ought to have been admitted before, at present he is in too serious a condition to be moved. I have been attending the poor man, but I do not see why I should attend parish cases without fee. If the parish is too large for one medical officer why not divide into districts? I am on the border of the parish and could do the work in this district.

Yours faithfully,

(Signed) —— ——.

*** The suggestion should not have been made by the practitioner that he would be happy to supersede the parish officer in part of his work. He was probably in ignorance of the circumstances and it would be unfortunate if the occurrence led to any personal ill-feeling between neighbouring gentlemen of the same profession.—ED. L.

ATTENDANT OR ADVISER.

To the Editors of THE LANCET.

SIRS,—The words "medical attendant" have been applied to medical men for many years by medical journals as well as by the public. Why medical men have allowed themselves to be addressed in this manner I am at a loss to understand. The word "attendant" is generally used in reference to servants in lunatic asylums and other establishments and is most confusing to the public who do not know whether it is the doctor or the servant to whom the term "attendant" has been applied. We never hear of clergymen or lawyers being addressed as attendants; they are called advisers. We cannot expect the public to respect us if we do not respect ourselves.

I am, Sirs, yours faithfully,

July 25th, 1898. MEDICAL ADVISER.

"A POINT UNDER THE EMPLOYERS' LIABILITY ACT."

To the Editors of THE LANCET.

SIRS,—With reference to the query of "A Hospital Surgeon" in THE LANCET of July 30th, *re* the power of entry to a hospital or private house by the employer's surgeon for the purpose of examining the injured person, &c., and your comment thereon which states that there is no obligation upon the patient to submit to it, there seems to be considerable confusion in the minds of your correspondents as between the "Employers' Liability Act, 1880," and the new Act, the "Workmen's Compensation Act, 1897." These are very different Acts both in title and working. If in your reply you mean the former Act "the Employers' Liability Act, 1880," no doubt your reply is correct enough. True, neither of the above, nor any other Acts, confer the power of entry into a hospital or private house for the purpose of such an examination without the occupier's consent, but with reference to the medical examination under the Workmen's Compensation Act, 1897, the patient "*(d) must submit to medical examination.* In order to prevent a fraudulent claim or as far as possible any malingering on the part of the injured workman it is enacted by the First Schedule that any workman who has given notice of an accident shall, if required by the employer, submit to an examination by a duly qualified medical man provided and paid by the

Digitized by Google

employer. If he refuses to submit to such an examination or obstructs it his right to receive compensation is to be suspended until such examination takes place. Schedule 1 (3). A similar readiness to submit to medical examination in this case either at the request of the employer or at the request of any person by whom the employer is entitled to be indemnified under the Act, is required from the workman from time to time whilst he is in receipt of weekly payments under the Act, subject to a like penalty in case he refuses or obstructs the examination. In this latter case if the workman objects to the employer's medical man or is dissatisfied with his certificate he may submit himself to one of the medical men appointed by the Government for the purposes of this Act, whose certificate is to be final and conclusive. Schedule 1 (11)." ("Ruegg's Employers' Liability and Workmen's Compensation," third edition, 1898. Butterworth & Co., Fleet-street, E.C. Price 10s. 6d.) A copy of the above Acts may be obtained for a few pence at any law stationer's.

I am, Sirs, yours faithfully,

Ilford, July 31st, 1898. MURTAUGH HOUGHTON, M.R.C.S. Eng.

"INCARCERATION OF THE PENIS."

To the Editors of THE LANCET.

SIRS,—A case almost precisely similar to that recorded by Dr. Theodore Floras (vide THE LANCET of July 23rd) came under my notice in the Bedford General Infirmary some three years ago. A man, aged forty-five years, had slipped the iron ferrule of a hoe or some such agricultural implement over the whole length of his penis "early in the morning." He was brought to the infirmary about 9 P.M. the same day in great distress, the organ enormously elongated, tense, blue-black in colour, and so suggesting a piece of strangulated intestine. The constricting iron band would not yield to any such instrument as bone-cutting forceps on account of its thickness and its situation prevented the employment of a file. Finally with difficulty a broad-grooved director was forced through the ferrule, and with the aid of a friend, a practical engineer from a neighbouring foundry, the metal was divided posteriorly with a keyhole finger saw. This done we found the ring too rigid to be bent back upon itself and so we had to continue the sawing anteriorly. After three hours' work the ferrule was removed in two halves. There was considerable loss of skin, especially over that part of the urethra which had been indented by the iron, and the resulting ulcer was a month in healing; no catheterism was necessary and the organ returned to its natural size in ten days' time. No stricture followed. The ferrule was 1¼ in. long, the same in diameter, ⅛ in. thick, and weighed nearly 2 oz.—I am, Sirs, yours faithfully,

Bedford, Aug. 3rd, 1898. G. H. GOLDSMITH, M.B. Cantab.

THE COLOUR OF NEGRO CHILDREN WHEN BORN.

IN the editorial columns of *Pediatrics* of July 1st it is remarked on the authority of Dr. Farabery, "whose statement will doubtless be supported by many medical practitioners who have had experience in negro obstetrical practice," that the negro baby at the time of its birth is of exactly the same colour as its white brother, and it shows signs of colour only after an interval usually of several days but often extending to many weeks. The evidence of a French physician, founded on experience obtained at a Soudanese village exhibited in Paris, was to the effect that the negro baby comes into the world a pale pink colour, the second day it is lilac, ten days afterwards it is of the colour of tanned leather, and at fifteen days it is chocolate-coloured.

THE PRINCE OF WALES'S TRAVELLING COUCH.

THE special carrying couch for the removal of the Prince of Wales from Marlborough House to the Royal yacht *Osborne* stationed at Portsmouth was constructed by Mr. John Carter, of New Cavendish-street, to whom it must be a great source of pleasure to learn that his appliance gave every satisfaction to the Royal patient.

A. B. C.—Since the researches of Döderlein and others have demonstrated the important part played by the vaginal secretion in the prevention of septic infection the tendency has been to limit the number of midwifery cases in which it is either necessary or desirable to employ vaginal or uterine douches. But a certain number of cases will be met with from time to time in which it may be advisable to use a douche; such cases, for instance, as are attended by some abnormality or in which the patient likes the sensation of comfort and cleanliness afforded by a daily vaginal injection. In these cases an irrigator should always be employed and it will be found if the can be suspended at a height of 3 ft. or so above the level of the patient's body that the pressure will be ample without being at all excessive. A metal Budin's intra-uterine tube should be employed. It admits of ready cleansing by boiling, and by its horseshoe shape allows of a free reflux of fluid from the uterus. A safe and at the same time efficient antiseptic to use is a solution of liq. io li of the strength of from 1 or 2 drachms to the pint of water. If perchloride of mercury be preferred the rule never to use it stronger than a solution of 1 in 1000 for the external genitalia, 1 in 2000 for the vagina, and 1 in 3000 for the uterus must be strictly adhered to, and care must be taken by compressing the uterus and by retracting the perineum to ensure that none of the solution be retained. Other antiseptics which may be employed either for the vagina or the uterus are carbolic acid solution of the strength of 1 in 80, or creolin of the strength of half a drachm to the pint of water.

Medical Diary for the ensuing Week.

OPERATIONS.

MOUNTJOY BREWERY, LTD.

(Late FINDLATER & CO.),

RUSSELL STREET, DUBLIN.

NOURISHING STOUT.

THE attention of Medical Men is respectfully called to the value of this finest of Malt drinks as a valuable Tonic Restorative. Numerous Unsolicited Testimonials have been received by our Bottlers all over England.

SAMPLES will be sent direct from the BREWERY, Carriage Paid, with name of nearest Bottlers, on application.

ANALYTICAL RECORD FROM "THE LANCET."

"CROWN STOUT.—MOUNTJOY BREWERY, RUSSELL STREET, DUBLIN.

"The nourishing qualities of Stout are due mainly to a comparatively high proportion of Malt extractions, which, consisting principally of maltose and dextrine, offer little task to the digestive organs. The sample before us is marked by an excellent proportion of these extractions, while, at the same time, the alcoholic strength is by no means excessive.

"The results of analysis were as follows: Malt extractions, 9·0 per cent.; mineral matter, 1·38 per cent.; alcohol—by weight 4·62 per cent., by volume 5·78 per cent.; equal to proof spirit 10·13 per cent. The mineral matters consisted almost entirely of soluble potassium phosphate. The Stout was in good condition, ripe, yet free from undue acidity, and possessed a characteristic malty flavour."

SIR CHARLES CAMERON'S ANALYSIS.

"DUBLIN.

"I have analysed a specimen of **Nourishing Dublin Stout**, submitted to me for that purpose by **The Mountjoy Brewery, Dublin.** I have never examined a specimen of Porter in which the solid or nutritive constituents were so abundant as in the case of this Stout. It contains **Ten Per Cent.** of its weight of solid matter, or nearly the amount of solids contained in milk. Its flavour is good, and it is **Remarkably Free from Acidity.**

"CHARLES A. CAMERON,

"*Professor of Chemistry, College of Surgeons, Dublin.*"

PROFESSOR TICHBORNE'S ANALYSIS.

"DUBLIN.

"I have examined and analysed for several years the Stouts brewed by **The Mountjoy Brewery**—viz, **Single, Extra,** and their speciality known as **Nourishing** or **Crown** Stout. The gravities of all these Stouts are very high, as proved by my analysis. **The Crown** or **Nourishing** Stout gave me one of the highest gravities I have ever seen in Stout. They are all of first-class quality. **The Nourishing** Stout being exceptionally fine, and owing to its **strength** and **purity,** is a most valuable food for **Invalids.** They are all brewed from **Malt** and **Hops only,** the water used being the best brewing water the City of Dublin affords.

"CHARLES R. C. TICHBORNE,

"*Professor of Chemistry, Dublin.*"

"APENTA"

THE BEST NATURAL APERIENT WATER.

APENTA WATER IN THE TREATMENT OF OBESITY.

"The *Berliner Klinische Wochenschrift* for March 22nd, 1897, speaking of some experiments made under Professor Gerhardt's direction in the Charité Hospital as to the value of APENTA water in the treatment of obesity, says that such experiments could not be carried out until quite recently, on account of the inconstant composition of the bitter waters coming into the market. In this respect, the APENTA water is favourably circumstanced, and it was chosen for these observations because of its constancy of composition. The conclusions arrived at as to the value of APENTA in the treatment of obesity, and as to its influence on tissue-change without causing any nutrient losses, were that it succeeded in producing a reduction of fat in the body without detriment to the existing albumen, and that the general health of the patient suffered in no wise, and the cure ran its course in a satisfactory manner."
—NEW YORK MEDICAL JOURNAL, Feb. 5th, 1898.

"REGIMEN FOR THE OBESE." Cards forwarded to the MEDICAL PROFESSION on application to

THE APOLLINARIS CO., LTD., 4, STRATFORD PL., LONDON, W.

HARVEY'S
SUGAR-FREE PALE ALE

(Protected by Her Majesty's Royal Letters Patent),

The only **ALE** which may be drunk with impunity by persons with whom, from various causes, ordinary Beer does not agree.

ABSOLUTELY FREE FROM SUGAR.

Mr. T. FAIRLEY, Leeds City and County Analyst, F.R.S.Edin., F.C.S., F.I.C., certifies, June 3rd, 1896, that this Pale Ale is

"ABSOLUTELY FREE FROM FERMENTABLE SUGAR."

For further analyses see THE LANCET, May 22nd, 1897, and the BRITISH MEDICAL JOURNAL, April 24th, 1897.

An article in THE LANCET says: "For years I have been unable to take beer as a beverage on account of the lethargy, indigestion, pain, and stiffness which invariably followed such indulgence; but for three months continuously I have taken one glass of this Sugar-free Pale Ale at luncheon without the slightest 'rheumatic' effects."
—THE LANCET, August 14th, 1897.

SPECIAL TERMS allowed to the Medical Profession, to whom a SAMPLE BOTTLE will be sent FREE on application.

The Sugar-free Pale Ale is supplied, upon receipt of cheque or postal order, in Imperial Half-pints, price **3s. 9d.** per dozen; Reputed Pints, **5s. 0d.** per dozen.

CHAMPAGNE

absolutely Free from Fermentable Sugar had been unknown to the Medical Profession

UNTIL THE

LAURENT-PERRIER

"SANS-SUCRE"

was introduced and commented upon by the BRITISH MEDICAL JOURNAL, THE LANCET, MEDICAL PRESS, and others.

All of which speak in most enthusiastic terms of the great progress made by the well-known firm of Champagne Growers, Laurent-Perrier & Cie., Bouzy-Reims, in producing a perfect Champagne of excellent Quality, Bouquet, and Taste, without the addition of sugar, alcohol, or liqueur.

CHAMPAGNE,

to the Medical Man the most important of all Beverages, and particularly valuable as a Stimulant Tonic, is now obtainable in such a form that it can be prescribed with advantage in most cases, and especially to those suffering from **Gouty** or **Rheumatic** pains, to the **Diabetic,** the **Dyspeptic,** and all those inclined to Acidity through Weak Digestion.

Professor Fresenius, of Wiesbaden; Professor Nothnagel, of Vienna; Dr. M—— G——, Dr. D—— S——, London; and many other prominent specialists have testified to the great value of the

LAURENT-PERRIER

"SANS-SUCRE."

Sample Bottle free and carriage paid, together with Pamphlet and Preferential Prices, to Members of the Medical Profession on receipt of Visiting Card.

Hunyadi János

A VERY INTERESTING and important contribution on Natural Mineral Waters of the purgative saline type was published in the report of a Special Analytical Commission in THE LANCET of December 5th, 1896. This report is made all the more interesting and reliable from the fact that a LANCET Commissioner personally visited the Saxlehner Springs, near Buda Pesth, and obtained samples on the spot, which were subsequently analysed in THE LANCET Laboratory, and the results obtained compared with samples purchased at a number of shops in London. The results showed that **HUNYADI JÁNOS, the Prototype of all Bitter Waters,** was, wherever it might be obtained, a water showing a **perfect uniformity of composition,** and one that could be **relied upon absolutely as at all times being identical** with that drawn from the Spring and fountain head. The numerous analyses in THE LANCET Report give very striking evidence not only of the **honesty of the water,** but bear out also the **remarkable uniformity of composition** that has characterised **HUNYADI JÁNOS** for a **third of a century.** Thus, the results recently obtained in THE LANCET Laboratory accord exactly with those obtained in Liebig's Laboratory over thirty years ago. **Nothing could be more satisfactory than this from the therapeutic point of view. Practitioners can thus depend** upon the water they prescribe, and may be assured that when **HUNYADI JÁNOS** is administered the **medicinal effects will always be the same,** and **with the same good results.** As is pointed out in the Report, an important feature in **HUNYADI JANOS** Water is the constancy of ratio of the active saline constituents to each other. The sodium and magnesium sulphates are together in almost exactly equal proportions, so **that what therapeutic property is lacking in the one is balanced by the other.** Neither the sodium sulphate nor the magnesium salt are in excess of each other. **In this way the purgative effect is not drastic,** but **mildly yet decidedly effective.** Again, besides these chief medicinal salts there are present in important quantity also in **HUNYADI JÁNOS** Water, Sodium Chloride, **Sodium Carbonate,** and **Lithium Chloride.** It cannot be doubted that each of these constituents contributes towards the **favourable action of the water,** which has for so long been a **distinctive and satisfactory feature attending its administration.** Last, but by no means least, the report of THE LANCET Commission shows that **HUNYADI JÁNOS** Water is bottled under **admirable sanitary precautions.** In the details of the analyses given there was not the slightest indication that **HUNYADI JÁNOS** Water contained any objectionable organic matter from whatever source. While therefore the medicinal properties of **HUNYADI JÁNOS** as a natural aperient are **sure and reliable,** it is **safe** also from the very important fact of its **extreme organic purity.**

Angier's Petroleum Emulsion

WITH HYPOPHOSPHITES LIME AND SODA

IS INDICATED IN THE TREATMENT OF

PHTHISIS

IN ALL ITS STAGES.

It relieves the Cough and Fever, and is of undoubted efficacy in checking the Diarrhœa and Night Sweats; while it has great power to improve Digestion, Assimilation, and Nutrition. Bland, soothing, creamy, it is unobjectionable to the most fastidious patient and agrees with the most sensitive stomach.

PRESCRIBED BY EMINENT LUNG SPECIALISTS.

In two Sizes (6 and 15 oz.), of all Chemists.

FREE SAMPLES TO THE MEDICAL PROFESSION.

An Address

ON

TONE SENSATION WITH REFERENCE TO THE FUNCTION OF THE COCHLEA.

Delivered at the Opening of the Section of Physiology at the Annual Meeting of the British Medical Association at Edinburgh, July, 1898,

BY WILLIAM RUTHERFORD,
M.D. EDIN., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF EDINBURGH; PRESIDENT OF THE SECTION.

GENTLEMEN,—There are few chapters in physiology so interesting as that in which Johannes Müller in his "Elements of Physiology" discusses certain preliminary considerations relating to the general physiology of the senses, and expounds his classical theory of the specific energies—or, as we should now rather say, specific activities—of the sense organs. No doubt we are all agreed that the immediate cause of the specific sensations of the different sense organs must be referred to the different modes of activity developed in the several sensory centres, but how it comes about that the activity of cells in the auditory centre impresses our consciousness with a sense of sound, while that of cells in the vision centre impresses us with a sense of light is, as Müller stated, a "problem incapable of solution."

I am not going to discuss the production of specifically different qualities of sensation, but the production of different qualities of the same kind of sensation. This aspect of the question presented itself to Müller in the early years of this century (1826), as it had done to Newton a century earlier (1704). Although Newton was an opponent of the undulatory theory of light, strange to say he suggested an undulatory theory of nerve action in attempting to explain the production of different colour sensations. He supposed that light induces vibrations in the retina that are transmitted to the brain and there give rise to colour sensations that differ according to the length of the incoming vibrations. In referring to Newton's idea Müller observed that "such a hypothesis if at all tenable would find its first application in accounting for the different sensations of which a single sense is susceptible; for example, in explaining how the sensorium receives the different impressions of red, yellow, and blue and of acute and grave tones," but "that it is only with this application that the hypothesis is worthy of regard."[1] These thoughtful words of Müller were set aside and his theory of specific activities extended to the hypothetical explanation of different qualities of the same kind of sensation, first by Natanson in 1844, then by Helmholtz[2] in 1862, and afterwards by Hermann. The extended theory was so well stated by Hermann[3] in the edition of his "Physiology" published in 1878 that I cannot do better than quote his words: "It is necessary to ascribe to the stimulation of different nerve-fibres the different qualities of any given sensation; for example, the sensations of red and blue, of high and low tones, and hence to suppose that the specific energy of certain fibres aids in the perception of red, while that of others aids the perception of blue, for if it were not so we would be compelled to assume that one and the same nerve-fibre is capable of states of excitement that differ in quality, an assumption hitherto unsupported by facts. There must therefore be at least as many sensory fibres as there are simple qualities of sensation." Although this extension of Müller's theory originated with Natanson its general acceptance and persistent vitality is mainly due to the great influence of Helmholtz.

I had thought that we might perhaps on this occasion discuss the production of different qualities of the same kind of sensation as regards the senses generally, but I became convinced that the subject is too extensive to be taken up at one meeting. I therefore propose to confine myself to the sensations of tone. At the meeting of the British Association held in Birmingham in 1886 I gave a popular evening lecture on the Sense of Hearing in which I proposed a new theory of tone sensation in opposition to the well-known theory of Helmholtz. A short abstract of my lecture appeared in the *Journal of Anatomy and Physiology*[4] at that time, but although my theory has been accepted by a few physiologists, the majority, if I may judge from all the German textbooks and some of those by British and American authors, still adhere to the Helmholtz theory, although there are evident signs that the implicit faith so long prevailing is gradually growing weaker. I deem this a suitable opportunity for submitting my views on this subject to those who have specially studied anatomy and physiology and are able to criticise the opinions I may express. In so doing I must bear in mind that I may be addressing some who are engaged in the practical departments of medicine and who are on that account scarcely so familiar with anatomical and physiological detail as some of us are. I shall therefore endeavour to be as explanatory as may be compatible with brevity in discussing a complicated subject. Although our auditory sensations are highly complex we know that the physical agent by which they are induced is simply the increase and diminution of pressure characteristic of the waves of sound; and happily we now know that in all animals the peripheral mechanism adapted for the reception of sound essentially consists of modified epidermic cells with hair-like processes by which the sound vibrations are transmitted to the cells and the auditory nerve impressed.

STRUCTURE OF THE COCHLEA.

We are all deeply indebted to Gustav Retzius[5] for the splendid illustrations and elaborate descriptions he has given of the structure of the ear. I have found his work of the greatest value in the study of this subject. All are agreed that the cochlear canal, or scala media of the cochlea, is the terminal organ that enables us to appreciate musical sounds. In transverse section the canal is somewhat triangular and is bounded on one side by bone and on two sides by thin membranes—the membrane of Reissner, through which the sound waves enter the canal, and the basilar membrane, through which they leave it. The sound therefore crosses the canal. The basilar membrane supports the organ of Corti; I believe the membrane is nothing but a mere supporting structure, but another function so very different has been ascribed to it that I had better describe its structure minutely. Its main body consists of connective tissue fibres extending from the periosteum covering the osseus spiral lamina to that lining the outer wall of the cochlea. In all cases the chief fibres of the membrane are tense, closely adjacent, and directed across the cochlea. In man and some animals they form a single layer. In the reptile and bird there are two layers of fibres, with a narrow interval between them through which some fibres pass obliquely from the one layer to the other. In the rabbit there are two layers of fibres with connective tissue cells between them. We shall presently see how this complicated arrangement of fibres affects Hensen's theory of the peculiar function he has assigned to them. The fibres are completely covered on both surfaces of the membrane by epithelial cells. Those on the lower or tympanic surface are undifferentiated squamous cells, while those above it are in part differentiated into the organ of Corti.

We can best understand the organ of Corti by comparing its simpler structure in reptiles and birds with its more complex structure in mammals. In the crocodile, as described by Retzius, it consists of hair cells at its free surface, supported by a large number of ordinary columnar epithelial cells planted on the basilar membrane. The fibres of the auditory nerve are distributed to the air cells. Corti's membrane (membrana tectoria) covers the whole organ and the endolymph fills the remainder of the canal. In birds the structure of the Corti's organ is essentially similar to that of reptiles. That fact is of special interest because the power of appreciating musical sounds is so conspicuous in some birds. In mammals the much greater length of the cochlear canal permits of a far larger number of hair cells. Most of the supporting cells are specially modified into the pillar cells of Corti and cells of Deiters, each of them containing a stiff elastic fibre that gives a comparatively firm

support to the lamina reticularis, through which the hairs of Corti's cells project. The hair cells do not reach down to the basilar membrane, but rest on the shoulders of Deiters's cells and inner pillar cells of Corti, by which they are individually supported.

Since Corti's hair cells are the true auditory terminals through which the nerve fibres are impressed their structure is of special importance. Each cell has a thin envelope enclosing a nearly fluid protoplasm with a large nucleus deeply placed near the inner end of the cell and a clear-looking body termed Hensen's corpuscle near its free end. About twenty short, stiff, rod-like hairs project from the free extremity of each cell, their inner ends passing a very short way into the cytoplasm. Nerve fibrils terminate around the inner ends of the hair cells. Retzius was unable to trace them into the cells, but there must at all events be physiological continuity between the cell substance and the nerve. Since the sound waves reach the hair cells through Corti's membrane the nature of that membrane and its relation to the hairs are therefore important. At the apex of the bird's cochlea Corti's membrane has been shown by Retzius to be simply an otolith consisting of a soft organic matrix laden with calcareous particles. But throughout the completely developed portion of the cochleal canal the membrane contains no calcareous matter and is therefore better adapted for the transmission of vibrations. Retzius describes it as "homogeneous and semi-gelatinous" and states that the auditory hairs either project into or are in contact with it. If that be their anatomical relation the membrane and hairs must vibrate as one mass, like the membrane and ossicles of the tympanum. In the mammalian ear Corti's membrane consists of laminæ of homogeneous fibrils. In the cat a hem runs along the lower surface of the membrane next the hair cells. The inner margin of the membrane is firmly attached to the epithelium covering the spinal lamina, while its outer margin is loosely attached to Corti's organ external to the hair cells. The outer attachment is so slender and easily ruptured that the membrane is most commonly detached from Corti's organ in making sections. It is therefore difficult to be certain of the anatomical relation between the membrane and the hairs in the mammal, but probably they are in close relation, so that membrane and hairs may vibrate as one.

STIMULATION OF THE AUDITORY NERVE.

When the sound wave in its phase of condensation arrives in the scala vestibuli it is transmitted through Reissner's membrane to the fluid in the cochlear canal, thence through Corti's membrane, Corti's organ, the basilar membrane, to the fluid in the scala tympani and membrane of the fenestra rotunda. All these parts oscillate back again in the rarefaction phase of the wave. It is admitted that the wave arrives at Corti's organ throughout the whole length of the cochlear canal at practically the same moment. The short, stiff, auditory hairs probably transmit the vibrations of Corti's membrane to Corti's cells in the same manner that they are transmitted by the columella of the bird's tympanum from the membrana tympani to the membrane of the oval fenestra.

What is the precise function of Corti's cells? Do the sound vibrations induce chemical discharges within them that stimulate the nerve ends? If such were their mode of action we may reasonably suppose that they would have required a liberal blood-supply to maintain active chemical change, like the visual terminals in the retina. But, as a matter of fact, there is not a blood capillary in Corti's organ. Its lymph-supply is obtained from capillaries at some distance and its renewal probably takes place slowly. It therefore seems reasonable to dismiss the idea of any special chemical action in Corti's cells and to assume that their action is probably mechanical. Since the terminals of tactile nerves in the cutaneous touch corpuscles are stimulated by pressure without the aid of any intervening cells it is reasonable to suppose that in the ear the sensory apparatus is stimulated mechanically by the alternations of pressure in the sound waves. This view is supported by the observations of Ewald[6] that after complete destruction of the labyrinth and tympanic apparatus on both sides of the head in the pigeon the animal still gives signs of hearing sounds made at a distance, although care is taken to obviate any effect on the nerves of touch. But all signs of hearing disappear if the auditory nerve is destroyed on both sides by the local application of arsenical paste or croton oil. The inference, therefore, is that the fibres of the auditory nerve can be stimulated directly by sound conducted by the bones of the head. But although the auditory nerve detached from its terminals can be stimulated by sound, are we to conclude that Corti's cells are superfluous and that the sound may stimulate the nerve fibres in the organ of Corti directly? We might as well say that touch bodies in the fingers are superfluous because the ulnar nerve can be stimulated by pressure at the elbow. Hair cells appeared as the auditory terminals at so early a stage in the evolution of the animal kingdom that their intervention between the sound vibrations and the nerves must be essential for their proper stimulation. But one cannot tell whether they are simply transmitters of sound vibrations to the nerves or whether the sound vibration, as we know it, is within the protoplasm of Corti's cells translated into that unknown form of molecular vibration termed a nerve impulse.

TONE SENSATIONS.

Our auditory sense excels all others in the power of distinguishing different qualities of sensation. It can distinguish tones varying in pitch from 16 or 20 vibrations to 40,000 or even 60,000 vibrations per second. A good violinist can detect about 50 differences of pitch within the range of a semitone, implying that he can feel a difference due to half a vibration. But in some highly-trained ears the sensitiveness is even greater, so that differences of pitch due to a quarter or even one-sixth of a vibration can be felt throughout the ordinary scale (Luft).[7] How are we enabled to appreciate differences of pitch? As we all know, Helmholtz supposed that the same nerve-cell cannot give us two different sensations even of the pitch of tone and therefore a separate nerve-fibre and cell must be impressed to enable us to hear tones differing by, it may be, only the fraction of a vibration. This was his extension of doctrine of specified activities to explain the different qualities of tone sensation. To render his theory feasible he supposed that the cochlea must contain an immense number of minute resonators capable of severally responding by sympathetic vibration to all the tones we can hear. Each cochlear resonator was supposed to stimulate its own special nerve-fibre and this in turn its own cell in the brain. When he advanced that theory in 1862 the structure of Corti's organ was so imperfectly understood that Corti's pillars were supposed to be the nerve terminals. They increase very slightly in length from base to apex of cochlea (from 0·06 mm. at the base to 0·1 mm. at the apex), yet Helmholtz deemed that small difference sufficient for his theory. But when it was ascertained that no pillars of Corti occur in the bird's cochlea, and that in the mammal they are mere supporting structures apparently unconnected with nerves, the theory of their function as resonators had to be abandoned.

But the resonance theory was not allowed to drop. Hensen came to its support with a new suggestion. He showed that the fibres of the basilar membrane increase slightly in length from base to apex of cochlea and that they may play the part of resonators for tones of widely different pitch, although the shortest fibres are only about ⅛ mm. and the longest about ½ mm. in length. But the fibres are so heavily damped by layers of cells cemented to them on both surfaces of the membrane and along their whole length that they are ill-adapted for resonance. Hensen thought that the basilar fibres run parallel with each other and that they lie in a single layer like piano strings; but in the bird's cochlea there are two layers of fibres and irregular fibres running between them. It is impossible that systems of fibres so arranged can severally act as resonators. A nightingale would scarcely be able to learn its songs if it had to rely on the individual vibration of basilar fibres to enable it to appreciate tones of different pitch. But another argument strikes me as cogent against Hensen's theory. If Corti's membrane had consisted of a single layer of tense parallel fibres, each cemented to the hairs of a series of Corti's cells and varying much in length throughout the cochlea, Helmholtz and Hensen would not have been so unreasonable in ascribing stimulation of Corti's cells to a segmented vibration of the superjacent fibres. But the sound waves first encounter the comparatively lax membrane of Corti and after affecting the hair cells reach

Digitized by Google

the heavily damped subjacent basilar membrane, which is surely in a most unfavourable position for sound analysis.

I have observed in Ziehen's "Physiological Psychology"[8] that Corti's membrane is substituted for the basilar membrane in alluding to Hensen's theory. No one, so far as I know, has ever ascribed a power of sympathetic response to the fibrils of Corti's membrane. It is not a tense membrane; its fibrils are in laminæ and in the bird it is semi-gelatinous. Nor has anyone ascribed to the short rod-like hairs of Corti's cells the power of selective and sympathetic vibration. I believe they are the mere transmitters of all vibrations, whether simple or complex, to Corti's cells. I submit, therefore, that the minute structure of the cochlea places insuperable difficulties in the way of Helmholtz and Hensen's theory and I cannot but think that if Helmholtz had known the structure of the cochlea in mammals, but more especially in birds as described by Retzius, the resonance theory would never have been proposed.

But there is a physical defect in the theory of Helmholtz which he entirely overlooked; for example, if we sound three tuning-forks, giving the notes of a common chord—say C, E, G—each fork produces a simple tone due to a series of simple vibrations. The three sets of vibrations are compounded and enter the cochlea as a compound vibration. But although we have the compound sensation of a harmony we can discriminate its three constituent tones. Helmholtz inferred that the cochlea must analyse the compound vibration and that three sets of terminals and at least three different sensory cells in the brain must be affected. Harmony, however, depends on the relative frequencies of vibrations. It is strictly determined by the mathematical ratios of numbers. In the common chord of C, E, G, the numbers are 264, 330, 396 vibrations per second. Helmholtz never supposed it possible for the cochlear resonators to send these or any such numbers of impulses along their respective nerve-fibres. He abandoned the mathematical cause of harmony at the cochlea and imagined that it could be accounted for by the specific activities of cells in the auditory centre. When he published his book on "Tone Sensations" in 1862 he cannot have been impressed by a passage in Fechner's "Psycho-physics"[9] published two years previously (1860), containing these significant words: "The first, the fundamental, hypothesis is that the activities in our nervous system on which the sensations of light and sound functionally depend are—no less than the light and sound themselves—to be regarded as dependent on vibratory movements."

Helmholtz, in his book on the "Sensations of Tone," gives no evidence that he ever sought to determine how many impulses per second can be transmitted along a nerve; on the contrary, he shows quite clearly that he dismissed the subject without experiment. You can readily verify my statement by examining page 253 of the third edition of his work translated by Ellis and published in 1875.[10] Yet eight years before that edition appeared, his own assistant, Bernstein,[11] had made his researches on the nerve impulse by means of his differential rheotome and had ascertained that the electrical change which accompanies the transmission of a nerve impulse lasts only $\frac{1}{1000}$th of a second (0·0007 second) even when the nerve is powerfully stimulated. Therefore, even when tested in that manner 1400 perfectly discrete impulses can be transmitted per second in a frog's sciatic nerve. But Bernstein's method of experiment, though highly ingenious, is far too crude to inform us of the limit to the frequency of the impulses that a nerve is capable of transmitting. The question is, if a nerve can transmit, say, 1400 perfectly discrete impulses per second, is there any reason why it should be supposed incapable of transmitting 14,000 or even 40,000 per second to produce the highest audible tones? I imagine that if Bernstein had made his experiments before Helmholtz published the first edition of his book he could not have abandoned the mathematical cause of harmony at the cochlea, but must have believed that the vibrations produced by the several tones of a chord are continued into the brain. I believe he would have adopted this view of the matter even though he adhered to his theory of cochlear analysis.

THEORY OF HEARING SUGGESTED BY THE TELEPHONE.

Eighteen years ago (1880), while thinking over the great difficulties that beset the resonance theory, it occurred to me that the telephone might by analogy help us to better understand the action of the cochlea. The telephone transforms sound vibrations, however complex, into electrical currents of corresponding frequency, amplitude, and wave form, and these in turn are re-transformed into sound vibrations similar to those received. The theory of hearing which I was led to propose is that there may be no analysis of sound in the cochlea; that all the hair cells may be affected by every sound, simple or complex, and through them the sound waves translated into nerve vibrations of corresponding frequency, amplitude, and wave form; that in the sensorium the nerve vibrations give rise to sensations varying in quality with that of the incoming impulses. My theory has been termed the telephone theory of hearing, and no doubt it is a convenient term to distinguish it from the resonance theory, but I wish it to be understood that I never regarded the hair cells as transforming the mechanical vibrations of sound into an entirely different mode of motion analogous to electricity. The essential point in my theory is simply this, that there is no analysis of sound waves in the cochlea. Theoretically a single hair cell, nerve fibre, and sensory cell should suffice to give us all the different sound sensations; but probably the great number of auditory terminals and sensory cells renders us far better able to feel slight differences in the quality of sounds. My theory of tone sensation has the advantage of carrying the physical cause of harmony into the auditory centre, and the validity of the argument I advanced in 1886 was afterwards proved by Hermann by experiments on the production of differential tones.[12] When two discordant tones are simultaneously produced a beat is heard, and if the vibrational difference between the two primary tones be sufficiently great the successive beats give rise to the sensation of a third tone whose pitch is the vibrational difference between the two primary tones; for example, if the primary tones have respectively 880 and 1056 simple vibrations—namely, notes A^1 and C^2—the pitch of the beat tone is 176 simple vibrations—namely, the note F.

Hermann produced the two primary tones from two tuning-forks, with a third fork at rest, but capable of consonating to the beat-note if it had been produced objectively, but the third fork remained unaffected, although the observer heard the beat-tone loudly. He therefore concluded that if the beat-tone failed to excite a resonator outside the ear it could not affect any supposed resonator in the cochlea; consequently it must be a purely subjective phenomenon arising from the conflict of vibrations in the auditory centre. That experiment, which has been fully confirmed, proves that the auditory nerve transmits to the sensorium vibrations of the same frequency as the sound waves and that they produce in the auditory centre harmony or discord, according to their relative numbers. Hermann's conclusion from these experiments is "that there is no alternative but to drop the Helmholtz hypothesis of resonators in the ear, although so elegant."

Although the telephone theory of the action of the cochlea enables us to understand the production of sensations of harmony and discord it still leaves much that is in the highest degree obscure. The discrimination of pitch is a great difficulty. We all know that it varies greatly in different persons. Those who have little or no ear for music have been found unable to observe any difference of pitch between C and E of the scale, although there is an interval of 66 vibrations between them. On the other hand, a musician with an extremely good ear may by practice become so sensitive to pitch that he can detect a difference due to one-fifth of a vibration even when the vibrational frequency is 1000 per second. That fact is all the more remarkable, because when the vibrational frequency rises above 500 per second we cannot detect the individual vibrations, although we can readily feel a change in the sensation. The accurate and refined appreciation of pitch seems therefore to imply an exceptionally perfect molecular state in the cells of the auditory centre; but how it is that the consciousness is so sensitive to changes in vibrational frequency when the

individual vibrations are no longer perceptible must remain a mystery.

Galton's whistle is now frequently used by aurists for testing the upper limit of tone sensation. The pitch of its note can be readily varied by a screw which alters the length of the tube of the instrument by very fine degrees within a range of 12 mm., by which a series of high tones can be obtained with vibrational numbers from nearly 6500 to 84,000, making a range of three and a half octaves above G^4, its lowest note. In using the whistle I find it best to hold it about 2 feet away and somewhat in front of the meatus, for if held too near the puffs of the air produced by squeezing the elastic bag distract the listener during the production of very high tones. In an experiment on three persons with very acute hearing I found that A. heard the pitch of the note rise until the tube was shortened to 1·5 mm., but heard no higher tone. B. could detect changes of pitch until it was shortened to 1·45 mm., but when shortened below 1·4 mm. he heard no tone. C. could detect changes of pitch until the tube was shortened to 1·4 mm., but heard no note when shortened below 1·3 mm. According to the scale accompanying the instrument made by Spiller, London, 56,000 vibrations are produced when the tube is 1·5 mm. in length and at least 60,000 when it is shortened to 1·4 mm. I was surprised at the accuracy with which the listeners detected changes of pitch produced by turning the screw only 0·01 or 0·02 mm. when tones so excessively high were produced. The highest appreciable tone has been stated by Luft to be 41,000 vibrations, but Galton's whistle shows that far higher tones can be accurately distinguished.

Another difficulty is the discrimination of the constituents of complex auditory sensations. How are we enabled to distinguish the several tones of a harmony, since their vibrations are compounded and so arrive at the auditory terminals? Helmholtz believed it impossible to explain our discrimination of the three tones of a chord unless the cochlea analyses the compound vibrations into its three component sets of simple vibrations and transmits their effect to at least three different nerve fibres. But I have argued that the theory of cochlear analysis is attended by insuperable difficulty. It seems to me that we are compelled to entertain the theory that there can be no cochlear analysis and that sound waves, however complex, are translated into nerve vibrations of like complexity which produce in all the cells of the auditory centre a sensory impression that is, so to speak, the representation of the complex vibration. By education and experience we have acquired the power of recognising complex tone impressions such as the vowel sounds without being able to discriminate their components. We all know how laborious it has been for the mathematician to analyse the phonographic curves of the vowel sounds and show what their constituents really are. And we know also that, although our auditory sense has been supposed to have the help of a marvellously perfect instrument of sound analysis in the cochlea, it has not enabled us to discriminate the constituents of the vowel tones, which I think it ought to have done if each constituent tone were, so to speak, ringing up its own nerve cell.

The power of discriminating the components of complex tone sensations such as we receive from an orchestra is, I believe, acquired by practice, and the very fact that it is so difficult to acquire and so rarely acquired to any remarkable degree appears to me opposed to the theory of cochlear analysis and favourable to the theory of tone sensation which I have proposed.

PRESSURE PATTERN THEORY OF THE ACTION OF THE COCHLEA.

A somewhat different theory of the action of the cochlea was proposed by Dr. Waller[13] in 1891. He is disposed "to regard the basilar membrane as a long narrow drumhead repeating the complex vibrations of the membrana tympani and vibrating in its entire area to all sounds—although more or less in some parts than in others—giving what we may designate as acoustic pressure patterns between the membrana tectoria (Corti's membrane) and the subjacent field of hair cells. In place of an analysis by consonation of particular radial fibres (of the basilar membrane) it may be imagined that varying combinations of sound give varying pressure patterns comparable to the varying retinal images of external objects." I own that I have had great difficulty in seeing how the action of the cochlea is to be explained in Dr. Waller's theory. If the hairs of Corti's cells are to be subjected to different pressures in different parts of the cochlea dependent on the unequal vibration of a tense membrane it seems to me that such a membrane ought to be undamped and placed in contact with the hairs of Corti's cells on the side of the entering sound. But the basilar membrane is heavily damped and is reached by the sound wave only after having traversed Corti's cells. I have already used this argument against Hensen's theory and it seems to me to be no less applicable to that under consideration. But all our theories are open to criticism on a subject so obscure; none of us can say that we have a theory capable of explaining all the facts which have been ascertained regarding the cochlea, and this will become very evident when I have alluded to the results of experiments on animals and pathological observations on man.

[13] Human Physiology, third edition, 1896, p. 474.

EXPERIMENTS ON ANIMALS.

An elaborate series of experiments was performed on dogs by Baginsky[14] of Berlin. His method was to render the animals completely deaf in one ear by destroying the cochlea on that side. He then, in one series of experiments, destroyed the apical portion of the remaining cochlea and in a second series he broke away part of the promontory and destroyed the adjacent portion of the spiral lamina. The inflammatory processes which followed the operation caused many experiments to fail, but in some cases he succeeded in obtaining results that seemed to him reliable. The sensitiveness of the animals to tones of different pitch was tested by air conduction of the tones of pipes. They were completely deaf for some days after the operation, but most of them recovered their hearing to some extent. Their audition was minutely studied for several weeks, after which they were killed and microscopic sections made of the cochlea to determine the extent of the lesion and the condition of the uninjured portion. When he destroyed the apical turn and the greater part of the middle turn of the remaining cochlea the animals after being totally deaf for five or six days gave signs of hearing the very high tones C^5 and C^4. In the course of the second week they were affected by somewhat lower tones, such as C^3, but seldom by C^2, so that they were deaf to all the tones of a bass voice and all the chest notes of an ordinary tenor voice. The necropsy showed that in these animals the basal portion of the cochlea was apparently uninjured and Baginsky's conclusion is that the basal turn of the cochlea is devoted to the audition of the very high tones which lie quite above the ordinary scale, while the apical and middle turns enable the dog to hear all the ordinary and the deeper tones of the voice, thus supporting the theory of Helmholtz.

The cochlea can be reached far more easily in the guinea-pig than in the dog and experiments on that animal have been made by Corradi[15] and also by Stepanow.[16] Both observers took the reflex movement of the outer ear as an index of hearing. According to Corradi destruction of the apical portion of both cochleæ abolishes all response to deep tones, but the animal is still affected by high tones. His results, therefore, agree with Baginsky's; Stepanow, however, obtained entirely different results. In a large number of guinea-pigs he destroyed the apical portion of both cochleæ. Although many experiments failed owing to permanent deafness or other cause he had seven successful cases in which low as well as high tones caused the animal to move its ears. He found no evidence that the animals failed to hear tones of low pitch. Stepanow's results are therefore a complete contradiction of those obtained by Corradi on the guinea-pig and by Baginsky on the dog, and we shall see that Stepanow's conclusions are borne out by his observations on man. Baginsky[14] also made experiments on the basal portion of the dog's cochlea, but with results so uncertain that he would have done well to have deduced no conclusions from them. The anatomical conditions are such as might well render any such experiments futile. He desired to open the scala tympani in the basal turn of the cochlea and destroy the membranous spiral lamina there without permanently interfering with transmission of sound to the apical portion. After completely destroying the cochlea of one ear and injuring the basal portion of spiral lamina of the other many of the animals remained permanently deaf. Of those

Digitized by Google

that recovered hearing, some appeared to be as much affected by high as by low tones; others seemed less affected by high tones; while in a small number of cases they seemed at first to hear only low tones, but after two or three weeks they were also affected by high tones. In some of these cases he found the membranous spiral lamina completely disorganised at the seat of injury, yet from results so variable and unsatisfactory he concluded that the special function of the basal turn of the cochlea in the dog is to enable it to hear high tones, which is, of course, in accordance with the Helmholtz theory.

PATHOLOGICAL OBSERVATIONS ON MAN.

Observations on tone sensation in speechless animals must always be unsatisfactory; one therefore turns to pathological observations on man in the hope of finding data of greater value, but here also the evidence is contradictory. Stepanow[17] has recorded the case of a young man who had received a severe blow on his left ear which eventually led to exfoliation of the apical portion of the cochlea to the extent of one and a half turns of the tube. When Stepanow became aware of the nature and extent of the exfoliation he perceived that if the Helmholtz theory of tone sensation be true his patient ought to have become deaf in his left ear to tones of low pitch. He had the man's hearing tested in the presence of several colleagues, amongst whom were a physicist and a physiologist, and all were satisfied that the man could hear tones as low with his left ear as with his right ear. Indeed, the appreciation of pitch by his left ear seemed unimpaired. The observers agreed that the case gave no support to the Helmholtz theory as regards the apical portion of the cochlea. Gruber[18] has reported the case of a boy, aged fourteen years, from whose left meatus he removed a sequestrum consisting of the two upper turns of the cochlea. Notwithstanding the loss of so much of the cochlea the tones of tuning-forks, if sounded loudly, were still distinctly heard by air conduction when held near the left meatus. Gruber states that the pitch of the notes made no difference and that the boy could correctly imitate the note. Unfortunately the range of pitch of the tuning-forks used is not stated, so that we have no means of knowing the depth of pitch of the tones heard by the left as compared with the right ear, in which the hearing was normal.

There are, however, other cases by no less eminent observers who regard them as favourable to the Helmholtz theory. A case reported by Moos and Steinbrügge[19] is referred to in the books as showing that extensive nerve atrophy limited to the basal turn of the cochlea is associated with loss of the audition of high tones. I shall not trouble you with the complicated details of that case because the examination of the precise limits of tone sensation in the two ears appears to have been incomplete, and although the deafness to high tones was nearly as great on the one side as on the other the observers examined the cochlea on one side only instead of on both sides for comparison. The books, in referring to this case, assume that the nerve atrophy in the basal turn was the cause of the deafness to high tones; but singularly enough the two eminent aurists whom I have quoted regarded the nerve atrophy as possibly the result of inactivity owing to non-transmission of the vibrations of high tones through the labyrinth, because of the high pressure of the lymph which they were satisfied had been of long standing. In support of this hypothesis they refer to experiments made by Bernett under the direction of Helmholtz, who found that high artificial pressure of fluid in the labyrinth diminishes the transmission of the vibrations of low but more especially of high tones to the membrane of the round fenestra, and that when the pressure is greatly increased the vibrations of high tones are abolished. The possible lowering of the upper limit of tone sensation by increase of intra-labyrinthine pressure must therefore be kept in mind in the study of this subject.

Two important cases have been recently reported by Bezold[20] which appear to have been very carefully observed. One of the cases was that of a woman, aged sixty-five years, whose hearing was defective on both sides. The scale of audible tones was shortened at both ends, the lower tone limit for air conduction was raised to B in each ear, but there was apparently no shortening of the lower end of the scale when the tones were conducted to either ear through the bones of the head. Her upper tone limit was lowered on both sides about two octaves below the highest audible tone of Galton's whistle. The highest note heard by the right ear was given by the whistle at 6·4 mm., by the left ear at 6·3 mm., implying that with both ears she could hear very high notes of from 13,000 to 14,000 vibrations. Three weeks after the aural examination the patient died from pneumonia and the necropsy revealed complete immobility of the foot of the stapes from ossification of the orbicular ligament, which may have accounted for the deafness to low tones by air conduction. Bezold examined the cochlea and found "no nerve-fibres in the spinal lamina near the fenestra rotunda; and in the further course of the first turn there was a moderate increasing atrophy of the nerve-fibres. There was a trace of atrophy even in the second turn. The remaining nerve-fibres stained well with Weigert's method and Corti's organ was well preserved except in the first turn." He concluded that the atrophy of the nerve in the basal turn explained the deafness to the high tones.

Bezold's second case was that of a woman, thirty years of age, whose hearing had long been defective, especially in the left ear, through which she was unable to hear conversation. The sound of a tuning-fork (A^1) placed on the vertex of the head and on either mastoid process was not heard, showing that bone conduction of sound had no apparent effect on the labyrinth and auditory nerve of either side. The range of tone sensation in the left ear was shortened at the lower but especially at the upper end of the scale. She could only hear tones in the middle register extending from D to B^1, a range of nearly two octaves. The sound vibrations that affected her left ear therefore extended from 148 to 990 vibrations and there were no gaps in the scale within that range. On the right side the lower tone limit was C, almost the same as on the left side, but the upper limit reached to 2·2 mm. of Galton's whistle. Her right ear was therefore affected by vibrations varying from 132 to about 38,000. In both right and left ears the scale was shortened at its lower end by about two octaves and the diagnosis was "nerve deafness." The patient was seized with severe illness and died shortly after these observations were made. The left temporal bone was removed and prepared for microscopic examination, but the organ of Corti was not well preserved. The foot of the stapes moved normally. "There was extensive and well-marked nerve atrophy in the basal turn, less marked in the second turn and scarcely noticeable at the apex." Bezold regards the nerve atrophy in the basal turn as the cause of the deafness to high tones, which of course is in accord with the Helmholtz theory. He makes no allusion to the fact that there were no breaks in the scale of audible tones, although there was evident nerve atrophy in the middle turn. He expected to find nerve atrophy in the apical turn to account for deafness to tones at the lower end of the scale, because in this case their defect could not be due to ankylosis of the stapes. Failing to find any definite lesion there he surmised that "possibly there were changes in Corti's organ in the apical turn, which owing to its poor state of preservation escaped notice," or that "there might have been a central lesion to account for the defect in the lower register." He therefore assigned what he regarded as a definite cause for deafness to high tones, no apparent cause for the deafness to low tones, and no defect of tone sensation resulting from the atrophy of fibres in the middle turn. I think it unfortunate that in this case the right cochlea was not examined, since there was deafness to low but not to high tones in the right ear and an examination of its nerve fibres would obviously have been important.

The cases to which I have referred are sufficient to illustrate the great difficulty attending the problem of tone sensation, the mobility of the stapes, the pressure of lymph in the labyrinth, and the state of the sensory nerve apparatus are all capable of affecting our tonal sense. In the first case quoted from Bezold deafness to low tones conducted through the meatus was apparently due to ankylosis of the stapes. I have referred to the effect of high lymph pressure on the transmission of low but more especially of high tones through the labyrinth and the possible production of deafness to these tones from that cause. I have now, in the last place, to ask you to consider the conclusions which appear to be indicated regarding the function of the cochlea in aiding our perception of pitch. I believe I was justified in arguing twelve years ago that our sensations of harmony and discord cannot be reasonably explained unless we believe that the

Digitized by Google

auditory nerve transmits to the brain impulses of the same frequency as the sound vibrations. The proof of that has since been furnished by the experiments of Hermann on differential tones already referred to. But it by no means follows that the theory of cochlear analysis is thereby disproved; on the contrary, it merely compels the upholders of the Helmholtz theory to admit that if certain cochlear terminals are affected by vibrations of a certain frequency they must transmit to the brain impulses of the same frequency as the sound vibrations. Although the validity of my argument on this point be granted it still remains an open question whether certain auditory terminals are impressed by tones of a certain pitch or whether they are all impressed by audible tones of every pitch. If the observations made by Gruber, but especially those by Stepanow, are reliable and free from fallacy we should be obliged to conclude that the loss of the apical half or so of the cochlea does not involve deafness to tones of low pitch. The results of their observations are therefore hostile to the resonance theory and favourable to the telephone theory. On the other hand, the two cases observed by Bezold and that by Moos and Steinbrügge show that deafness to tones of high pitch may be associated with nerve atrophy in the basal turn of the cochlea. It is very difficult to look upon that association as a mere coincidence and apparently more reasonable to regard the basal portion of the cochlea as necessary for the appreciation of tones of high pitch. But if a corresponding relation cannot be shown between the apical portion of the cochlea and tones of low pitch the upholders of the resonance theory must feel that they are supported by only one of the two legs that are necessary in this case.

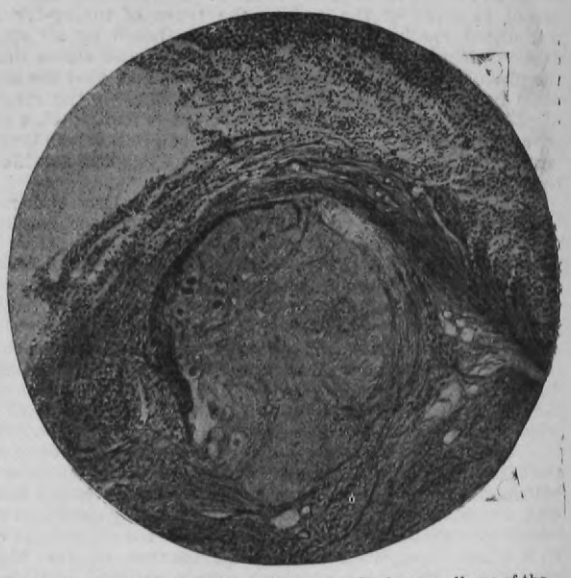
But if it appear impossible to harmonise the resonance theory of the cochlea with anatomical structure and with certain pathological observations how does it stand with the telephone theory? If it be true, as Gruber and Stepanow would have us believe, that the basal turn of the cochlea can enable us to hear all tones, notwithstanding destruction of the apical half, it seems reasonable to expect that the apical portion should still enable us to hear all tones, notwithstanding nerve atrophy in the basal portion. Bezold's cases, however, appear to show that the basal portion is necessary for the appreciation of high tones. We are therefore landed in the dilemma that pathological observations on the apical portion of the human cochlea are opposed to the resonance theory and favourable to the telephone theory, while those of the basal portion favour the resonance and oppose the telephone theory. In Bezold's second case only about two octaves of audible tones remained in the middle register; the loss of high tones was ascribed to nerve atrophy, but no cause could be assigned for the loss of low tones. On the telephone theory one is compelled to ask why there should have been deafness to many low and so many high tones, although nerve fibres enough remained to enable the patient to hear two octaves of the middle tones. If evidence of high tension in the labyrinth had been recorded in that case an explanation could have been found on the lines of Bernett's experiments, but in absence of that evidence I am bound to say that I do not at present see how that case is to be explained on the telephone theory.

Whatever be the true theory it is important to note that tone defects are far less common at the lower than at the upper end of the scale and that in the middle of it they are exceedingly rare. Politzer states that in cases of apparent tone defects in the middle register the use of resonators generally shows that there is only diminished sensitiveness instead of total deafness to the particular note. At first thought one might be inclined to regard gaps in the scale as evidence in favour of the theory that each auditory fibre is concerned in the sensation of a particular tone, but in the well-known case reported by Magnus, where the tones F, F sharp, G, G sharp, A sharp and B were inaudible, ankylosis of the stapes and calcification of the orbicular ligament were found after death and assigned as the cause.

I think I have said enough to show the difficulty of arriving at a definite conclusion regarding the extension of Müller's doctrine of specific activities to the several fibres of the cochlear nerve. The writing of this address has been to me a grateful task, for it has compelled me to see the strength and the weakness of the theories hitherto advanced in explanation of the function of the cochlea. The study of theories stimulates thought and I trust that my necessarily rapid and imperfect sketch of a complicated subject may serve to induce discussion of the difficult problem of the qualities of tone sensation.

ON THE

OCCURRENCE OF CARTILAGINOUS AND BONY NODULES IN THE TONSIL.



BY HUGH WALSHAM, M.A., M.D. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN (FORMERLY PATHOLOGIST) TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST; CLINICAL ASSISTANT TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

WHILE making some observations on the occurrence of tubercle in the tonsil other interesting points connected with their histological structure came under my observation, such as the number and distribution of the tonsillar crypts, the varying amount of adenoid tissue, and the gradual disappearance of the closed lymphatic follicles with advancing life; the occurrence of the so-called epithelial pearls so well described by Professor Kanthack[1] and their relation to the formation of the tonsil calculi, &c. But in two instances examined by myself the microscopical structure of these organs was so peculiar that I venture to regard them worthy of record, especially as I am unable to find any description of such a condition in medical literature, at least in this country.

The first case which came under my observation was that of a man, aged fifty years, who died from acute pulmonary

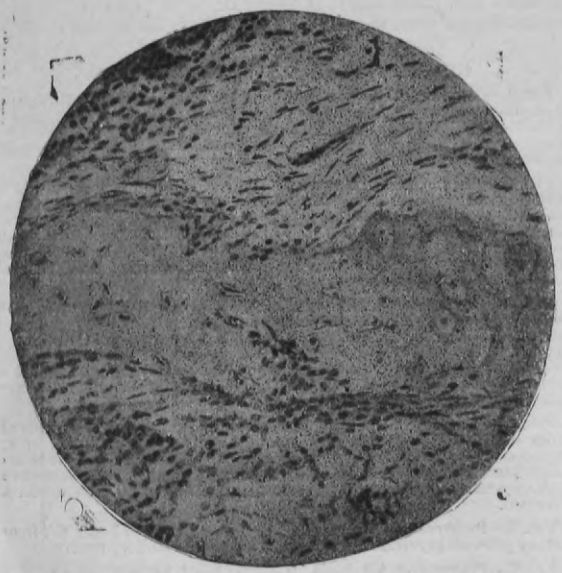
From the man aged twenty-seven years. It shows well one of the cartilaginous masses in the adenoid tissue of the tonsil.

tuberculosis in the City of London Hospital for Diseases of the Chest. The post-mortem examination was made on Oct. 3rd, 1895. Both tonsils had undergone considerable atrophy or perhaps may more properly be said to have retained their infantile conformation. The tonsillar crypts were extremely few and wide. The squamous epithelium lining the crypts was normal. The closed lymphatic follicles had for the most part disappeared, but this is perhaps only a senile change described by Retterer.[2] Scattered throughout the organ, at the base of the crypts, were numerous small masses of bone in the form of trabeculæ, rings, and solid nodules. These nodules and trabeculæ of bone did not encroach on the proper adenoid tissue of the organ. They were just discernible with an ordinary pocket lens in the stained section as small yellow nodules. In one section a small cartilaginous nodule was still to be seen, having apparently not yet been converted into bone (see Fig. 2).



As at this time I was working exclusively at the occurrence

of tubercle in the tonsil this peculiar histological structure was merely noted for investigation at some future period. My interest in the subject was, however, again aroused in the following month by the occurrence of another example of a somewhat similar condition. The post-mortem examination of this case was held on Nov. 25th, 1895. The subject was a man, aged twenty-seven years, who died in the hospital from chronic pulmonary tubercle. Both tonsils were somewhat atrophied. The crypts with their lining epithelium were normal. Most of the closed lymphatic follicles had tumbled out during the process of mounting. In this instance there were scattered throughout the adenoid tissue of the organ large masses of cartilage which could be very easily distinguished with a lens magnifying about four diameters (see Fig. 1). In places the cartilage had been converted into bone. The matrix of the cartilage appeared in some places to be of the hyaline variety, but in others it could only be described as fibro-cartilage. The cartilaginous nodules were surrounded by strands of dense fibrous tissue which formed a kind of perichondrium. Some of these cartilaginous nodules, unlike the former case, penetrated the adenoid tissue of the organ and in one part they nearly reached the epithelium lining the free surface of the tonsil. I was at first much

FIG. 2.

From the man aged fifty years. It shows one of the cartilaginous nodules passing into bone.

puzzled with this condition of the tonsil and at first supposed I had to do with a new growth—in short, with an enchondroma of the organ, a rare condition no doubt, but one that has been described by pathologists. But on thinking over the matter I came to the conclusion that this supposition was untenable as the cartilage and bone trabeculæ occurred on both sides. On reflection it appeared to me that there was a close analogy between these cartilaginous masses in the tonsils and those small cartilaginous growths which develop in the lines of the branchial clefts and which are found in the neighbourhood of the ear, or lower down in the neck, sometimes only on one side, but more rarely symmetrically placed on both, or enclosed in the so-called branchial cysts and also to the masses of cartilage that are found in the parotid gland. The tonsil, according to Professor His,[3] is developed very early in intra-uterine life—about the fourth month—by a simple folding in of the mucous membrane at a spot situated between the second and third branchial arches, and the remains of which are visible in the adult tonsil as a fold, the plica triangularis. As development proceeds this primary infolding of the mucous membrane or primary crypt splits up at its base into numerous secondary crypts and by the swelling of the meso-blastic tissue lining the invagination and by the early appearance of lymphoid follicles the rudimentary tonsil is formed. Remembering then the position in which the tonsil is developed, I think we may assume that these cartilaginous nodules are of fœtal origin, that is, they are cartilaginous rests derived from the second branchial arch.

After a search through foreign medical literature I have been able to discover three similar examples. Two of these were observed by Professor Roth[4] and one by Dr. H. Deichert[5] and all of them from the Pathological Institute of Göttingen. The first of Professor Roth's cases occurred in a man, aged fifty-nine years, who died from fracture of the skull; the tonsils were found to contain bony trabeculæ. The other case was that of a child, aged two years, sex not stated, who died from diphtheria. It is unfortunate that these two cases are only very shortly reported; but it is stated that the tonsils of the child contained mostly cartilage, although a little bone was also found. The third case, reported by Dr. H. Deichert, was that of a man, aged seventy-seven years, who died from aneurysm of the aorta. Large cartilaginous and bony masses were scattered throughout the organ. This peculiar fœtal inclusion is no doubt rare, but perhaps commoner than one would at first suppose. My two examples occurred in 34 consecutive post-mortem

FIG. 3.

Also from the same man. It shows one of the bone trabeculæ at the base of the tonsil.

examinations and Dr. Deichert says in a footnote to his paper that he had heard of two other similar cases after his communication had gone to press.

I think there can be no doubt that the enchondromata that have been described as occurring in the tonsil must have their origin in these cartilaginous rests which from some unexplained reason begin to grow and proliferate. Clinically it is, I think, important to remember that this condition may occur in the tonsil as a congenital peculiarity. The bony trabeculæ, it will be observed, were principally found in persons of advanced age, and at first one would be disposed to look upon the presence of bone as a mere senile change; but it was also found to a less extent in the younger persons. I think it probable that these centres of ossification may be present from the first, as a small amount of bony material was found in the tonsils of the child aged two years observed by Professor Roth.

Professor Kanthack, to whom I showed the microscopical specimens, dissents altogether from the above theory. His view is that in these cases there is no embryonic inclusion, but merely a metaplasia of fibrous tissue into bone or cartilage. The accompanying micro-photographs show clearly this peculiar structure of the tonsil.

THE BACTERIOLOGY OF PROGRESSIVE CIRRHOSIS OF THE LIVER.[1]

WITH ILLUSTRATIVE PLATE.

BY J. G. ADAMI, M.A., M.D. CANTAB., F.R.S. EDIN.,

LATE FELLOW OF JESUS COLLEGE, CAMBRIDGE; PROFESSOR OF PATHOLOGY, MCGILL UNIVERSITY; PATHOLOGIST TO THE ROYAL VICTORIA HOSPITAL, MONTREAL.

IT is needless for me here to enter into a discussion of the various theories which have been adduced to explain the causation of cirrhosis of the liver. I need only say that the experience of a large number of investigators who for weeks and months have inoculated or treated animals with various alcohols have shown that alcohol itself induces at most the fatty liver with, it may be, a very slight amount of fibroid change in the portal areas and that not a single observer has been able by this means to produce anything at all resembling the extreme deposit of fibrous tissue which we meet with in the hobnailed liver. Alcohol in the main leads to the fatty liver, while, on the other hand, the evidence has steadily accumulated, notably in India, that extreme cirrhosis may attack children and adults who have never taken a particle of alcohol either medicinally or otherwise.

Within the last few years the French school of pathologists headed by Hanot have regarded the enlarged cirrhotic liver with jaundice as being of infectious origin, and it is common nowadays to speak in France of *le foie infectieux*, but to the best of my knowledge no one has as yet described any one micro-organism as being found frequently associated with these cases of so-called infectious liver. At most Levi[2] from a case of cirrhosis in a seventeen-year old male, with marked periportal fibrosis and enlarged spleen, obtained a diplococcus pathogenic for guinea-pigs. The age of the patient, the proliferation of the bile-ducts and the absence of ascites would indicate that this case was one of what is termed "Hanot's cirrhosis," but the bacteriology is rendered somewhat doubtful in that there was also present bacterial endocarditis of the pulmonary valve and suppurative meningitis. Unfortunately I have not been able to obtain the original paper; nevertheless, this brief statement of the main features of the case makes it at least possible that the endocarditis and meningitis and the presence of diplococci in all the organs may have been due to a complication. On the other hand, there is a somewhat suggestive relationship between these cases of Hanot's cirrhosis and epidemic jaundice, in some of which observers have noted the presence of a diplococcus or bacillus with polar staining. To the best of my knowledge no one has as yet recognised the frequent presence of any form of micro-organism in the commonest form of hepatic cirrhosis, the so-called portal cirrhosis tending to the production of the hobnailed liver with or without marked atrophy of the liver.

On behalf of the Government of the Dominion of Canada I spent the summers of 1894 and 1895 in Nova Scotia investigating a very remarkable disease affecting the cattle in a limited area of the country—the so-called "Pictou" cattle disease—of which the main lesion is a singularly extensive cirrhosis of the liver. The disease is only found in a district spreading along the northern coast of the peninsula, in a tract of country about forty miles long by from five to twelve miles broad. There apparently it has been noticed for some forty years, now at one end of this area, now at the other. The disease would seem to be very chronic and not to affect all the cattle upon the farm simultaneously, but unless due precautions are taken in the course of three or four years most of the cattle will one after the other be affected. It would seem further that the disease does not spread directly from animal to animal, for there appears to be no special incidence of the cases following upon the long winter sojourn of the animals in the byres, which, with rare exception, are miserably dark and ill-ventilated, the attempt being made to keep these as warm as possible in consequence of the severity of the winter. One or two cases are on record in which the disease has broken out in a neighbourhood after the body of a cow affected with the disease has been washed down by one of the streams and stranded upon farm lands. The gradual extension of the disease from farm to farm through any given district seems to be largely brought about by the fact that each farm has at the back of it a belt of woodland in which the cattle roam during the summer. These belts are badly fenced off from each other and if an animal is affected it attempts to wander off into the woodland and there die in a remote corner. Thus unless precautions are taken the carcasses of these animals remain uninterred and appear to act as centres of infection. Under the present Government regulations notification is given of every suspicious animal, and the Government inspector if satisfied that it is a case of the disease immediately destroys the beast and burns the carcass or has it buried in quicklime. By this means the number of animals affected is steadily being reduced, so that within the last few years the number of cases occurring annually has sunk from 150 to under 30. As for the symptoms of the disease the first which is to be noticed is that the milk acquires a peculiar bitter taste and has a distinctly acrid odour upon boiling. Within a few days the animal becomes dry, it is weak and listless, the coat stares, the limbs are dragged, the bowels are loose, the abdomen is a little swollen, the eyes are staring, and the conjunctivæ are subicteroid. The weakness deepens and the animal dies apparently in a condition of complete exhaustion. In some few cases death is preceded by a period of intense excitement, almost maniacal in character, the animal rushing about charging at obstacles and then falling into a condition of paresis followed rapidly by death. I killed and made post-mortem examinations upon some 30 animals during the two years and found, as Dr. Osler and Dr. Wyatt Johnston previously determined, that the main lesions are an extreme condition of generalised cirrhosis, not only periportal but pericellular, the organ being somewhat enlarged and having a smooth or more rarely a finely granular surface. There is evidently an abundant production of thin bile, for with scarce an exception the gall-bladder was found to be very full and the fæces well stained. The periportal and abdominal lymph glands in general are large and succulent, there is a moderate amount of ascites, the fluid being particularly clear and limpid, and together with this there is a rather remarkable condition of gelatinous œdema of the mesenteries and intestinal walls. A further constant lesion is the presence of numerous follicular ulcers in the fourth or true stomach. These, save in the very acute cases, are found in a cicatrised condition giving strongly the impression that the earliest lesions of the case are gastric and are followed by the infection of the abdominal lymphatic system and the portal area. The spleen is not markedly enlarged. From all the animals which I killed I was more fortunate than my predecessors in gaining a characteristic micro-organism. This may have been due to the fact that I employed a somewhat different method of making my cultures. Instead of taking the media

[2] Archives Générales de Médecine, March and April, 1894.

DESCRIPTION OF ILLUSTRATIVE PLATE.

FIG. 1.—Microbe of Pictou Cattle Disease from isolated colony upon glycerinated agar roll tube inoculated from bile of diseased cow; stained with Ehrlich's gentian violet. Photograph under Reichert's $\frac{1}{12}$ in. immersion. The bacteria are seen, some as ovoid bacteria, the majority as diplococci surrounded by a faint halo.

FIG. 2.—Pictou Cattle Disease. Section of liver of cow killed while suffering from the disease, stained with carbol fuchsin for 24 hours, bleached in sunlight for six weeks after mounting. Photograph under Reichert's $\frac{1}{12}$ in. immersion. A few of the diplococcus forms can be well seen surrounded by a faint halo. These appear to be largely within the liver cells. With a magnifying glass the position of several others not in focus can be made out.

FIG. 3.—Pictou Cattle Disease. Section of liver of rabbit inoculated intraperitoneally with pure cultures of the microbe and dying 21 days later. Treated like the preceding and photographed under the same magnification. Innumerable diplococcus forms in the main within the liver cells, some, not perfectly in focus, seen as ovoid bodies, others as dots (end on ?). The varying size apparently is due in part to polymorphism, in part to unequal bleaching.

FIG. 4.—Progressive Cirrhosis in Man. Section of liver from case of more diffuse cirrhosis than the preceding; treated similarly. *a.a.* Diplococcus forms within degenerating liver cells. *b.b.* The same in the immediate neighbourhood of what appears to be fusiform connective tissue nuclei. *c.* Group of diplococcus forms obscurely seen within a liver cell.

FIG. 5.—Progressive Cirrhosis in Man. A culture, 48 hours old, from kidney juice on glycerinated agar showing diplo-bacillary form.

FIG. 6.—Progressive Cirrhosis in Man. Slide preparation, 24 hours old, isolated colony on agar glycerinated and inoculated from liver juice. Preparation shows transitional forms, bacterium (ovoid), diplococcus, and bacillus.

Digitized by Google

and inoculating on the spot I employed a series of sterilised glass pipettes in which I collected relatively large amounts of the juices of the various organs, ascitic fluid, blood, &c., and then when back in my temporary laboratory, either upon that or the following day, I inoculated my media. By this means, constantly from the lymph of the abdominal glands and from the liver juice and more rarely from other organs and fluids, I obtained in each case growths of a characteristic micro-organism, small and polymorphous, at times appearing as a diplococcus, at other times as a stumpy bacillus or diplo-bacillus. This by its polymorphous character gave me a considerable amount of trouble until I found that employing the same broth or agar tube at the end of twenty-four hours I obtained the one form and at the end of forty-eight hours the other, while also the depth of the stain employed altered the appearance. Further study showed me that this micro-organism was in reality a short bacillus with polar staining, in this resembling to some extent the micro-organisms of hæmorrhagic septicæmia in the lower animals, but unlike them possessing a slight capsule. I was able to grow this upon all the ordinary media of the laboratory (Fig. 1). Into the characters of this micro-organism I will not here further enter, beyond stating that I found it pathogenic for rabbits, guinea-pigs and mice, rabbits dying in from 15 to 25 days and guinea-pigs in from 30 to 35 days on an average. The characteristic features of this disease, the ascites without jaundice, the gastric and intestinal disturbances, and the condition of the liver led me seriously to consider the similarity between the clinical history in these cases and that present in portal cirrhosis in man, and though it may seem a small matter I was especially struck that the first post-mortem examination which I performed upon a case of atrophic cirrhosis upon my return from Nova Scotia exhibited the same gelatinous œdema of the mesenteries and intestinal walls which was so prominent a feature in the Pictou cattle disease.

Thus on and off for the last three years my attention has been directed towards the possibility of discovering bacteria in ordinary progressive portal cirrhosis, and, indeed, upon three occasions I have thought that I had gained specific micro-organisms. In two, unfortunately, the growth became contaminated with the colon bacillus, and as they occurred on the eve of my vacation I was unable to continue the search further. In the third, which occurred in June of the present year, the growth was very slight and, although pure, it had apparently died out by the fifth day and I was unable to gain any further cultures. The difficulty which has pursued me in this search has been that which has prevented me from publishing so far any extensive report upon my studies on the Pictou cattle disease—namely, the extraordinary difficulty in staining the micro-organisms in the tissues. I have tried a very great number of methods and while with many I have been able to recognise the bacteria the results obtained have been so inconstant that I have felt that others following my steps might possibly have negative results. Thus I have been unwilling to make any full statement until I should be able to state clearly how to recognise the micro-organisms.[3] While this micro-organism stains deeply it appears to lose its stain even more rapidly than does the tissue. Sometimes Gram's or Weigert's method shows the micro-organisms brilliantly, but while the iodine appears to have a deterrent effect upon the decolourisation of the microbes the stain is not properly fixed by this means; and while, again, I have obtained good results by staining in methylene blue dissolved in anilin oil, momentarily passing the sections so stained through a mixture of anilin oil and xylol, through xylol into Canada balsam, even here the colour appears to fade out rapidly, so that in a few days the micro-organisms are unrecognisable. Eventually the thought struck me that bleaching in the sunlight might be a possible means. By this process there would be no diffusion currents set up and if, as my previous work had shown, the bacilli took up the stain with rapidity then the deeply-stained sections would have so much of the dye in the bacilli that upon bleaching out the bacilli would be left stained when the tissue itself had become colourless. My laboratory assistant, Mr. E. W. Hammond, prepared a large series of sections in this way and obtained some excellent results. He found that, as I had suggested, strong staining with carbolised fuchsin followed by bleaching for a short time each day for a period of a fortnight or more demonstrated the bacteria admirably.[4] While the process is a slow one it is one which has the undeniable advantage of allowing the mounted sections to be examined each day so as to determine how far the process of bleaching has progressed. By this means I was able to find out that in the Pictou cattle disease the micro-organisms while present scattered through the new fibrous tissue are present also in large numbers within the liver cells, and in the liver of a rabbit which had been inoculated with the micro-organism isolated by me, although the animal died before any marked cirrhosis had developed, the liver cells were seen to contain these microbes in very great numbers (Figs. 2 and 3). As to how the micro-organisms enter these cells, or whether truly they are within the cells or in the minute biliary canaliculi which permeate them (and so truly outside the liver cells), is a point upon which at present I can throw no light, but the appearance given, which will be seen in a specimen under the microscope in the pathological exhibit, is that these cells contain large numbers of extremely minute diplococci.

Only quite recently a remarkable case of cirrhosis with pigmentation unaccompanied by diabetes has again drawn my attention to the bacteriology of atrophic cirrhosis. Dr. Maude Abbott, who is working in my laboratory at the Royal Victoria Hospital, showed me some sections of the abdominal lymph glands stained by Weigert's fibrin stain in which under a high power I noticed a peculiar fine granulation, and upon examining with $\frac{1}{8}$ in. immersion these fine granules resolved themselves into minute diplococci. Examining the liver stained similarly I there noted large numbers of the same micro-organism and since then I have gone through all the five cases of cirrhosis which I have had during the last three years, through specimens of five most characteristic cases of hobnailed liver received from Professor Hektoen of the Rush Medical College, Chicago, and through a series of sixteen livers, some of well-marked atrophic cirrhosis and others of milder stages of cirrhosis, courteously sent me by Dr. Flexner from the Johns Hopkins Hospital. So far in every case of well-marked portal cirrhosis, whether of the small shrunken type or the large hobnailed type, whether associated with jaundice and without ascites or with ascites without jaundice, I came across constantly one characteristic form of micro-organism, obtaining the best and most permanent results by the method I have already mentioned of staining in carbolised fuchsin and bleaching or partially bleaching in the sunlight. Here I gladly acknowledge the assistance I have received from Mr. W. M. Abbott and Mr. C. Nicholson in preparing and staining this material. Mr. Nicholson, who will demonstrate illustrative specimens in the Pathological Museum, finds that he obtains the surest results by using Ziehl-Nelsen carbol-fuchsin, either pure for five hours or diluted with an equal bulk of water for from twelve to eighteen hours, washing in absolute alcohol, then through xylol into xylol Canada balsam. Mr. Hammond's method was very similar. The time necessary to bleach of necessity varies. Working in winter Mr. Hammond required from a fortnight to a month. In the powerful sun of Montreal in July Mr. Nicholson found two days sufficient, and even then the process had gone too far, the microbes being decolourised. On the whole, therefore, sections cut frozen gave surer results than those prepared in paraffin, the irregularity in thickness of the former ensuring that some portions are bleached to the desired extent. This micro-organism is extraordinarily minute. By the trained eye in well-stained specimens it can be just recognised under the $\frac{1}{12}$ in. immersion lens, but for satisfactory work it is absolutely necessary to employ the $\frac{1}{8}$ or $\frac{1}{5}$ in. immersion lens. According to the depth of the stain so does it appear either as an ovoid bacillus, which might easily be mistaken for some stained deposit in the liver cells, or as a minute diplococcus surrounded by a distinct halo, the explanation being that with strong staining the bacillus and capsule are stained throughout, and with weak staining the body of the micro-organism and the capsule are decolourised, leaving simply the polar staining. Even in the tissues these micro-organisms are somewhat polymorphous—that is to say, at times one sees the two stained portions so close together as to resemble a minute edition of the

[3] Reports upon my observations are given in the Reports of the Dominion Department of Agriculture for the years 1894 and 1895.

[4] It is but simple justice to Mr. Hammond to state that, while I suggested this method, the carrying out of the process was wholly his. But for his zeal my investigations would be far less advanced.

Digitized by Google

gonococcus, at other times they are farther apart and appear rounded like the coccus form of the pneumococcus, while in the same specimen a rare form may be seen in which the two stained portions are even slightly elongated. These are present in greatest numbers within the liver cells but occur also in the new connective tissue, sometimes in cases where there is much small-celled infiltration in localised patches, where they are present in great numbers, sometimes along fine channels which I can only regard as lymphatic capillaries. So far I have not recognised them in the bile-ducts, although by analogy with the Pictou cattle disease, in which I not unfrequently gained cultures from the bile, it is not improbable that some at least escape from the liver by this means. In one liver received from the Johns Hopkins Hospital Mr. Nicholson tells me that he recognised them definitely within the smallest bile-ducts. One remarkable feature about them, one which years ago I noted in connexion with the Pictou cattle disease, is that whether they be seen in the lymph glands or in the liver they have in the unstained condition a distinctly brownish tinge, so that in the liver especially these bodies may at first sight be mistaken for minute granules of precipitated bile pigment. They vary in number; in two cases in which the disease appeared to be of very slow progress but few were present; in those cases in which the bands of portal connective tissue showed an abundance of small round cells and in which the disease according to all indications was active and progressive the number was remarkable—in fact, so great that it was impossible for me to arrive at any other conclusion than that there is a distinct association between the presence of these micro-organisms and the development of the disease. So minute are these micro-organisms that it is extremely difficult to focus them and I would strongly urge those attempting to confirm these observations to take from twenty minutes to an hour studying an individual field of the microscope before arriving at any conclusion. Indeed, I know of no form so minute save that recently described by Nocard and Roux as being the causative agent in the contagious pleuro-pneumonia of cattle, and the strain upon the eyes in studying these microbes is most severe. This adds greatly to the difficulty on photographing the micro-organisms.

I am indebted to Dr. Patrick, the photographer of our hospital, for the accompanying lantern slides, in which, despite great difficulties, he has managed, I think successfully, to demonstrate the organisms in the tissues, but with regard to this I may say that where he shows one micro-organism the slightest change of focus would bring others into view, so that his slides show but about 1-20th of the number recognisable in any given field. The drawing, made under the camera lucida from the centre of the field reproduced as Fig. 3 in plate, will give an idea of the frequency of these microbes.

As to whether the micro-organisms in the human and in the bovine liver are identical it is impossible for me to affirm. At the Johns Hopkins Hospital as in our own hospital and in a large number of foreign hospitals, not to mention the leading hospitals in the old country, it is now the custom to obtain cultures from half-a-dozen or more regions, including the liver, in every necropsy performed within fifteen hours after death. And while the methods employed for obtaining cultures are in many cases faulty, to the extent that an insufficient amount of tissue juice is taken, it seems to me unlikely that had this form been cultivable upon the ordinary media it would not before now have been isolated. Nevertheless there is this to be said, that very frequently the colon bacillus grows upon cultures made from the liver; isolated colonies of the micro-organisms from the Pictou cattle disease, while growing more slowly, are not unlike those of the colon bacillus, and thus possibly the micro-organism, if growing in a manner similar to that of the Pictou cattle disease, might be neglected on account of this similarity in appearance.

It so happens that in Montreal cases of the disease are few and far between; five cases only have come under my notice in four years, and in a series of 934 necropsies made during twelve years at the Montreal General Hospital and indexed by Professor Wyatt Johnston, I find that altogether 31 cases of cirrhosis of the liver are recorded and 14 of the cirrhotic and fatty liver, with 1 recorded as "hypertrophic cirrhosis." I have thus thought it wise to publish these observations, even though I can at the present moment make no absolute statement with regard to the isolated micro-organism and its characters beyond the statement that, as already mentioned, in one agar tube made from the liver juice I was able to recognise the form although in not very great numbers and with the absence of any visible growth.

Lastly, as to the cases in association with which I have found this micro-organism. If future observers confirm the observations given above then we must conclude that many of the divisions and distinctions attempted to be drawn between the forms of advanced cirrhosis of the liver must be broken down; for, in the first place, I have found the same appearances in the large liver with moderate granulation or slight hobnailed condition which some would speak of as "hypertrophic cirrhosis"; as again in the small contracted typical hobnailed liver; in cases frankly multilobular with sharply defined bands of connective tissue cutting off relatively large areas of liver substance and showing relatively few bile-ducts; as again in cases of the more unilobular type with ill-defined edges to the lobules and abundant bile-ducts; in cases which have shown jaundice without ascites, ascites without jaundice, and again both jaundice and ascites; and, lastly, in cases with a pronounced alcoholic history and others in which no history of alcoholism could be obtained.

I am far from wishing it to be understood that I am here laying down that all cases of fibroid change in the liver present these minute micro-organisms; to make any such suggestion would be absurd. Nor, again, am I prepared to say that Hanot's cirrhosis affecting the young adult and presenting an enlarged liver with smooth surface and, accompanying this, crises of icterus is identical with the more ordinary form of progressive cirrhosis affecting the adult. It may be so or it may not. After forty years of age cirrhosis is, according to my investigations, accompanied by the presence in the liver cells, as again in the newly-formed connective tissue, of an extraordinarily minute bacillus having a polar staining and resembling greatly in its appearance under the microscope a form which I isolated from cases of infective cirrhosis among cattle.

I cannot conclude without again expressing the debt under which I labour to several helpers. To Dr. Maude Abbott and to Dr. Patrick; to my laboratory assistant at the University, Mr. E. W. Hammond, who aided me very materially in Nova Scotia; to Mr. Howell, my assistant at the Royal Victoria Hospital, but for whose energy I should have been unable to prepare and examine all my material; to Mr. Nicholson, who has most gladly crossed the Atlantic to demonstrate my specimens during the course of the meeting; and, above all, am I indebted to a member of the McGill University, my predecessor not only in the chair of pathology, but also in the investigations in the Pictou cattle disease, than whom none, not even myself, could more willingly or more appropriately or better have brought this subject before you.

APPENDIX (*July 12th, 1898.*)

By a remarkable coincidence, upon the afternoon of the day upon which I completed the dictation of the foregoing paper in order that I might have it complete for Dr. Osler to take with him to Edinburgh I was called to perform a post-mortem examination upon a case apparently of heart failure which turned out to be one of atrophic cirrhosis of the liver. I should here add that a diagnosis of cirrhosis of the liver had been considered and had been left in doubt, while clearly, from the condition of the heart, death had resulted from failure of that organ. Not to enter too fully into the details of the case—for the clinical notes of which I am indebted to Dr. James Stewart—I may say that the body was that of a female, aged fifty-six years, who had always lived in Canada, and who, after the diseases of childhood, had until two years previously enjoyed good health. She had ten children with no miscarriages and there was no history of inherited disease. She gave a moderate history of alcoholism, stating that she chiefly drank beer, but if one may base any argument upon the frequent presence of minute whitish plaques scattered along the œsophagus she was a pronounced alcoholic. For the last two years she had not been well, dating her impaired health from a fall while out walking when she injured her back somewhat. For the last year her heart had been very weak and upon exercise her feet and legs became swollen. Since last April the weakness, swelling of the legs and abdomen, shortness of breath and palpitation had been much worse, and for three days before admission to hospital dyspnœa, sleeplessness, and weakness had been extreme, while for months she had steadily been losing flesh. Upon admission she was found to be sallow

in appearance, with moderate anæmia of mucous membranes; the sclerotics were icteroid with distension of the superficial vessels; the face was emaciated and there was orthopnœa. The temperature was normal, the pulse was rapid and the respirations were 36. The skin, more especially of the face, neck and arms, was of a peculiar ashy colour. This, she stated, had been noticeable for some years; there was slight general œdema, marked œdema of the lower extremities, and definite ascites. The pulse was 100, very irregular in volume and rhythm, and the apex-beat was not recognisable; there were no murmurs. There was evidence of right-sided pleurisy and there were numerous coarse and fine râles with expectoration of frothy mucus. There was frequent vomiting and retching, though this had begun only a few days before admission to hospital. The urine was dark, amber-coloured, with flocculent sediment, a fine ring of albumin, and it contained some bile. For a week or more her condition improved; the heart became more powerful and the ascites diminished. Suddenly, upon July 6th, the patient died.

The necropsy was held six hours after death and showed the following conditions. The heart was large, full, with dilatation of the cavities, the muscle being somewhat atrophied and fibroid. The coronary vessels were atheromatous. All the valves were normal and in both auricles were puriform and breaking down ball thrombi indicating a very feeble circulation. Both lungs showed adhesions to the diaphragm and elsewhere and on section presented little beyond œdema save that the lower lobe of the right lung was almost completely compressed and airless as a result of a right-sided pleurisy. The right pleural cavity contained about 700 c.cm. of red-stained fluid without flocculi. The abdomen contained between 900 and 1000 c.cm. of turbid and greenish ascitic fluid. Neither liver nor spleen were visible. The stomach was long and narrow with mucosa thickened, the cardiac portion having a curious strawberry-like appearance with fine white dots standing out but not projecting from the generally reddened surface. This faded off in the pyloric portion of the stomach where there was a fair amount of mucus. The first three inches of the duodenum presented an identical strawberry-like appearance to that seen in the cardia. The small intestine in general was congested and the last 3 in. before the ileo-cæcal valve showed large prominent solitary follicles. The walls of the small intestine had a distinctly browish tinge as of von Recklinghausen's hæmochromatosis. The mesentery of the small intestine was not only fatty but markedly swollen and upon section abundant milky lymph poured out wherever it was cut. The abdominal lymph glands were in general reddened and succulent. The retro-peritoneal glands, especially those in the neighbourhood of the portal fissure, and of the pancreas, were markedly enlarged. The liver was distinctly small, weighing 1045 grammes or a little over 2 lb.; the two lobes were correspondingly diminished in size, the organ was pale and had a finely granular surface, and there were abundant old fine veil-like adhesions over the upper surface to the diaphragm. On section the organ cut fairly firmly, more especially along the lower half of the right lobe and the under surface. On the whole the appearance on section was more fatty than fibroid. Microscopically the organ presented along with fibroid thickening of the portal sheaths a somewhat diffuse cirrhosis, the bands of fibrous tissue not being sharply cut and being infiltrated with a considerable number of small round cells. The cirrhosis was very obvious, but not of the more usual type, and the diffuse nature of the change may explain why the surface was finely granular rather than distinctly hob-nailed. The gall-bladder had œdematous thickened walls. The spleen was of normal size and rather soft, although on section the trabeculæ were seen to be larger and more prominent than usual. The pancreas was voluminous and moderately firm. The suprarenals were of fair size. The kidneys were of the hog-backed type of mixed interstitial and parenchymatous nephritis. This so-called hog-backed appearance is that which, as I believe Formad of Philadelphia was the first to point out, is the more common form of alcoholic kidney in North America. The organs were large with a finely granular surface and full and firm cortex. There were white infarcts both in the kidneys and the spleen. The body was still warm at the time of the holding of the necropsy and I obtained numerous sterilised pipettes of tissue juice from the liver, spleen, kidneys, abdominal lymph glands, ascitic fluid, pleural fluid, pericardial fluid, blood, and lymph from the mesentery, and with these I made a series of inoculations on the surface of sloping glycerinated agar tubes as also some into broth. While I have not had time to examine all the organs microscopically for bacteria I have studied the liver and there found the same diplococcus forms which I have already described as being recognisable in the cirrhotic liver. Portions of the collected ascitic and pleural fluid were centrifugalised, the cellular débris dissolved by caustic potash, and after further centrifugalisation the deposit was examined under the microscope after staining with carbolised fuchsin. This deposit showed rather rare minute diplococcus forms with a slight halo round them similar in all respects to those recognised in the tissues.

A series of slide preparations was made from the various pipettes direct, fixed in the usual method and stained with carbol fuchsin, which was warmed until definite vapour was given off, then washed with water just cool enough to bear the hand in it, and mounted. As a result the characteristic diplococcus form was found in the preparations made from the liver, lymph from the mesentery, the ascitic fluid, the heart blood, the left kidney, and the mesenteric glands; they were not found in the pleural cavity, the bile, or the pericardial fluid. Next, using a fair amount of the fluid out of each pipette I allowed this to flow over the surface of slanting glycerinated agar tubes, my experience with the Pictou cattle disease having shown me that while the fluid in the pipettes could show numerous diplococci, apparently the majority of these are dead and only a few remain alive. By this means in 24 hours I obtained fairly frequent growths in tubes from the spleen and left kidney and rare growths in the mesenteric glands and heart blood. Two colonies only appeared upon the tube prepared from the liver and four from the ascitic fluid and this latter did not show clearly till the expiration of forty-eight hours. Subcultures made again directly upon the glycerinated agar surface showed a fine, rather thin growth at first of minute discrete colonies; later these ran together into thin waxy lines which, upon the expiration of four or five days, assumed a faint yellowish tinge.

Other tubes were made directly from the pipettes of the kidney and spleen into beef broth. This upon the following day showed a faint turbidity, which just, as in the case of the Pictou cattle disease, if anything lessened with further growth, while a whitish deposit formed at the bottom. Since then, using the remaining pipettes, I have obtained a great number of broth cultures, the growth being much more free upon this medium than upon the agar, and, further, yielding forms which are more characteristic and less liable to cause confusion, for the micro-organism is most remarkable in its characters.

Grown upon broth in 24 hours it is present in the form of minute diplococci surrounded with a faint halo or capsule. Often these tend to be arranged in irregular chains in which the separate couples of dots are not quite regularly arranged, the long axis joining the two dots not of necessity coinciding with the long axis of the chain. Grown upon glycerinated agar the appearance is most puzzling, and although I had a similar experience when working out the character of the micro-organism of the Pictou cattle disease these agar cultures have given me a week of profound anxiety until within the last 24 hours I have solved the problem. A 24 hour culture at 37° upon glycerinated agar reveals minute forms which upon careful staining with fuchsin, not too deep, are clearly formed of a diplococcus (Figs. 5 and 6). One gets every transition, from the frank diplococcus form through one in which only very careful focussing shows that the somewhat oval bacterium has at either pole a deeper stained mass (Fig. 6) to forms in which the polar staining cannot be made out so that one appears to deal with true short bacilli (Fig. 6). In addition to this a certain number of oval forms can be seen still smaller than the diplococcus in which the distinction between the two ends cannot be made out. In 48 hours, and still more in 72 hours, the same culture which had given this appearance at the end of 24 hours appears to be contaminated by the presence of long distinct bacilli—that is, if sections be well stained with fuchsin, while this is still more the case after staining with Löffler's methylene blue. At first sight a culture from this variety showing these bacilli of irregular length with rounded ends, often lying side by side, appears to be undoubtedly of the colon bacillus of some allied form. And here I gain an explanation of the contrary results obtained by a bacteriological *confrère* and myself made in London two years ago. I took to him cultures isolated from two cases of cirrhosis which on examination in Montreal seemed to be diplococci, and his statement that he found only colon bacilli made me cease my investigations for the time. I can now well understand his most pardonable mistake.

Digitized by Google

Yesterday, upon examining the agar-plate culture from the spleen, which had been made upon July 7th, had been left for 24 hours in the incubator and there apparently yielded no growth, and it thus had remained for 4 days at the ordinary temperature in the shade, I recognised one form of growth extremely minute, the colonies well separated from each other. Upon removing one colony and making a coverslip preparation stained with fuchsin I found that I had to deal with long chain-like bacilli interspersed with some shorter forms of the same breadth. The appearance was so wholly unlike anything that I had previously made out in the broth cultures that I neglected this colony and made a culture from another identical in appearance and equally isolated, and in this case, after staining with fuchsin, and as I thought over-staining, I washed in absolute alcohol. The result obtained was most remarkable. The long bacillary forms could still be recognised in this as in the other specimen, and if anything they were longer, but each long filament showed a discoloured sheath in which, scattered at not perfectly regular intervals, were pairs of dots deeply stained. In some places individual dots could be clearly recognised, in others they were fused into short deeply stained lengths. These pairs of dots in size resembled the diplococcus-like forms seen in the broth cultures and in the tissues to which I have already so frequently drawn attention. I regret that time has forbidden that I should obtain photographs of this very curious appearance so that they could be demonstrated with the lantern. In the series of preparations which will be found in the Pathological Museum this form will be placed under the microscope and there will also be a series of sketches made by me under Zeiss's camera lucida showing this appearance. I touched the same colony with a platinum needle and inoculated a broth tube from it and eight hours later, the broth having in the meantime been kept at 37° F., it showed a faint turbidity, and now some specimens treated with carbolised fuchsin in the same way showed in place of the singularly long filament of the original colony numerous diplococcus forms, fairly large, in which the connecting, more colourless portion could be well seen, while here and there is a rarer form showing three instead of two dots along the course of the bacillus. These observations satisfactorily explain the curious condition of affairs. The microbe which is seen in the tissues as a diplococcus surrounded by a faint halo is in broth after twenty-four hours present also as a diplococcus of the same size, rather larger, showing or not showing the halo according to the extent of the stain. Upon agar-agar, while first present as a diplococcus form, it gradually extends and each day is seen as a longer bacillary form, but if stained and decolourised with carbolised fuchsin, and decolourised to the right extent, each long filament is seen to be made up of diplococcus-like members lying in a common sheath. I made out a similar condition of affairs in connexion with the Pictou cattle disease, but do not remember to have met with such long filamentous forms.

We seem thus to be dealing with a form totally unlike any which, to the best of my knowledge, has been described; the polymorphism is remarkable. It is most difficult, however, to determine how to describe the appearances seen, and I am at a loss whether to state that we are dealing with an encapsuled diplococcus or with a bacillus having inclusions taking a peculiar deep staining, just as in the ordinary cell the nucleus stains deeper than the surrounding protoplasm. The general appearance in the tissue is certainly that of an encapsuled diplococcus, but, on the other hand, grown outside the body and upon agar and then treated with Löffler's methylene blue the whole of that portion which plays the part of a capsule to the diplococci takes on a stain with as great intensity as do ordinary bacteria. On the whole, at present I am inclined to the latter view, because examining tubes in which proliferation is most rapidly proceeding I find upon staining with carbol fuchsin and decolourising with alcohol that one has in those youngest ovoid forms what is most suggestive of the polar staining such as one sees, for example, in the bacteria of hæmorrhagic septicæmia—that is to say, there is at either pole not a complete coccus form but a generally deep staining concavo-convex segment, the two parts being separated by a clear space, and the membrane joining the ends of the opposite crescents being clearly visible. If this form coincides in other respects with the micro-organism of Pictou cattle disease it will grow rather more easily upon slightly acid media, it will grow upon serum and very slowly in gelatin without marked liquefaction and will be fatal for animals of the laboratory at a relatively long period after inoculation. It so closely resembles the micro-organism of the Pictou cattle disease that I feel that I may safely prophesy this. The time taken in unravelling the mutability of growth upon agar-agar has prevented me from working out these points during the last few days.

The great similarity in appearance presented by growths upon agar-agar under ordinary staining to the colon bacillus may perhaps make it necessary to say a few words about the relationship of the micro-organism isolated by me to the bacillus in question. I have made growths side by side and find that in broth the colon causes a greater turbidity; it appears to grow more freely upon agar-agar and also to be endued with greater motility. Upon staining an 18-hour broth culture of my micro-organism by the Nicolle Morax method in order to demonstrate flagella I found the micro-organisms which are even more stumpy than the colon bacillus under similar circumstances to be possessed of either one or two terminal flagella, but not of lateral. This if it were necessary would seem distinctly to prove that the micro-organism is wholly distinct from the colon group. However, I make this statement provisionally and will give fuller details as to the characters of the micro-organism within the next few months, probably in the *Journal of Experimental Medicine*.

I trust, however, that I have said sufficient to prove:—1. That in at least a very large number of well-marked cases of progressive cirrhosis in man there is to be found largely within the liver cells and also in the lymph spaces in the newly formed connective tissue a peculiar and very minute form of micro-organism, presenting on staining to the proper extent the form of a diplococcus surrounded by a faint halo or when stained deeply being a rather obscure ovoid bacterium, which may easily be mistaken for stained deposits within the cells. 2. That in the infective cirrhosis of cattle a very similar micro-organism is recognisable, present in like positions within the tissues and showing similar appearances when stained. 3. That from at least thirty cattle affected with this disease I have been able to isolate the micro-organism from the liver, bile, abdominal lymph glands, and in some cases from the various organs in the body. 4. That the micro-organism isolated from these cattle is a polymorphous micro-organism, appearing as a small diplococcus when grown upon broth, and tends to assume a distinctly bacillary form when grown on solid media. 5. That this micro-organism is pathogenic for the animals of the laboratory, and that in them it is to be recognised within the hepatic cells as in other regions. 6. That from a case of distinct atrophic cirrhosis in the human being I have been able to isolate from various organs of the body a similar micro-organism, which grown in broth has a diplococcus form and grown upon agar is present as a short or longer bacillus according to the age of growth.

This is not the occasion for me to discuss at length the bearing of these observations upon the nature of progressive cirrhosis in man. It is only necessary for me to say that if they are confirmed, as personally I feel they must be confirmed by everyone who proceeds with sufficient caution to follow the methods employed by me, then cirrhosis of the liver assumes an entirely new aspect. We gain a satisfactory explanation at once of such phenomena as the enlargement of the spleen, which, as has already been noted, by more than one observer, may be made out before there is any sign of portal obstruction; we see why so frequently there should be right-sided pleurisy and may even find that the question as to whether a case is complicated with ascites or jaundice depends upon this micro-organism, depends upon whether it sets up a low inflammation of the peritoneum or whether it more especially affects the liver cells and the bile-ducts, while disturbances which may occur not immediately in connexion with the liver—in the pancreas and in the kidney, for example—would seem to gain a possible explanation from the fact brought out by me that this micro-organism, while frequent in the liver cells, is in an advanced case to be gained from the heart blood and from the kidney. That the micro-organism only causes cirrhosis I do not believe; indeed, we may find that it is the cause of more than one disturbance in the liver and indeed in other organs. This I base upon the fact that in the case in which I have isolated this form from man the micro-organism shows itself capable of existing in several regions of the body; in fact, of setting up what bacteriologically we regard as a septicæmic condition.

DIABETIC COMA SUCCESSFULLY TREATED BY SALINE TRANSFUSION; NO RELAPSE FOUR WEEKS AFTERWARDS.

BY THOMAS OLIVER, M.A. DURH., M.D. GLASG., F.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

IT is the general experience of those who have had to treat diabetic coma by saline transfusion that while consciousness may be restored this is of short duration, for the individual after a few hours lapses back into coma, from which a second saline injection fails to arouse him. In putting the matter thus I believe that I am only stating what has been the experience of most physicians. There have of course been exceptions and I venture to record the following case because the notes relate rather an unusual experience—viz., that at the time of writing the patient has remained perfectly intelligent during the twenty-eight days which have elapsed since the transfusion.

A man, aged thirty years, was on June 25th, 1898, admitted into the Newcastle-upon-Tyne Infirmary under my care suffering from diabetes of fully eight months' duration. Nine months ago he became very thirsty and began to drink large quantities of water. He would frequently drink three large bottlefuls of herb beer at a sitting and his night's rest was broken by his being obliged to get up to assuage his thirst. Eight months ago, as he found himself getting weaker, he gave up work. For the previous eleven weeks he had been very constipated, a condition hardly relieved by aperient medicine. Since his thirst became established he had passed large quantities of urine and he had lost weight to the extent of 4 st. There was nothing of importance in the patient's family history. Beyond having had pleurisy five years ago and two mild attacks of influenza since, he had been a very healthy man, and although he had lost flesh he was still well covered. His skin was dry and lemon-coloured, his tongue was dry and covered with a white fur, and the saliva, which was acid, did not contain any sulphocyanic acid. Upon his thighs there were several brown patches, the remains of pustules which came out a few months before. The knee-jerks were absent, the heart and lungs were healthy, and the skin of the abdomen was at places chocolate-coloured. The liver dulness was normal and the splenic dulness was slightly more pronounced than usual. The patient was placed upon diabetic diet and codeia, and on the whole appeared to make fair progress. On the afternoon of July 12th he left the infirmary in order to go home by rail, a distance of thirteen or fourteen miles, but he was brought back to the infirmary the same evening in a state of coma. He had, it appears, reached the station all right, but there he must have become confused, for a few hours afterwards he was found in a railway carriage at Tynemouth in a state of unconsciousness and on a different line of railway from that by which he should have travelled. Dr. Rowell, the house physician, recognising the patient who had left the infirmary only a few hours previously and finding him comatose, at once transfused him with two and a half pints of saline solution, passing it slowly into the right median basilic vein, and also freely purged him. The saline solution was composed of one drachm of chloride of sodium to one pint of boiled distilled water, the temperature of which was reduced to 112° F. During the operation the patient became sufficiently revived to complain that he felt pain. Before the transfusion his pulse was beating at the rate of 45. By degrees consciousness was regained and has since been retained. For the first three days after the transfusion a very small quantity of urine was passed daily—only 21 oz. instead of from 140 to 200 ounces when he was first in the infirmary. As the patient was known to be suffering from diabetes it was unfortunate that his urine was not examined on his readmission during and immediately after the coma, but the day afterwards it was found to be free from albumin and acetone, although containing sugar. Since then the amount of urine passed has gone up by leaps and bounds until he passed daily 190 oz. On July 15th the skin on the back of his hands was rather more bronzed than usual, the pulse was 52, markedly dicrotic and compressible, the tongue was dry, and the saliva was acid. The pupils were slightly dilated. The urine on July 15th was acid and its specific gravity was 1025; it contained sugar, but neither albumin nor acetone. On July 18th the patient complained of slight numbness in the right hand, but while there was slight anæsthesia there was no analgesia, although there was quite distinct paresis of the extensor muscles of the wrist compared to those of the left hand. There was very slight wrist-drop.

The case is interesting mainly on account of the length of time consciousness has been retained since the transfusion, which is a cogent reason why in diabetic coma such a line of treatment should be adopted. Not only was the patient rescued from a condition which in all probability would have proved fatal, but he has been so restored that had he been a wealthy man with a will to make or business matters to arrange he would have been able, with his present state of health and clearness of intellect, to accomplish it. I regret that there is no mention on his clinical chart of the quantity and the character of the urine passed in the twenty-four hours for the two days prior to his leaving the infirmary. In most cases I have noticed that before diabetic coma supervenes the patient passes a very small quantity of urine compared to what he had passed previously and that usually this urine contains albumin. Sometimes, indeed, there is almost complete suppression of the secretion of urine. During diabetic coma if a catheter is passed into the bladder perhaps only a few drachms of urine are drawn off, which contains both sugar and albumin. Then for the first time we learn from the nurse that no urine has been passed for the previous twenty-four hours or more. While therefore I do not deny that diabetic coma may be due to acetonæmia caused by the presence of diacetic acid in the blood, I am disposed to regard it rather as the result of a mixed toxæmia in which uræmia plays not an unimportant part. Professor Bedson found albumin, sugar, and acetone in the urine of one of my own patients, but no trace of acetone or its congeners in the blood, which, considering the supposed relationship between acetonæmia and diabetic coma, is rather an interesting fact. I should like, in conclusion, to draw attention to a fact of therapeutical interest, and that is the influence which cocaine often has in overcoming the obstinate constipation of diabetes. Where aperients fail, cocaine in small doses (¼ gr. twice or thrice daily) will not only brace up the muscular system generally and remove the sense of fatigue so frequently present in these patients, but act so decidedly upon the musculature of the intestine that its peristalsis is increased and constipation is overcome.

Newcastle-upon-Tyne.

THE OCCURRENCE OF ERYTHROMELALGIA IN DISEASE OF THE SPINAL CORD; AN ACCOUNT OF TEN CASES.

BY JAMES COLLIER, M.D., B.Sc., M.R.C.P. LOND.,

JUNIOR HOUSE PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

THE association of erythromelalgia with symptoms indicative of lesions of the central nervous system has been so frequently observed that the opinion of recent observers supports the opinion originally put forward by Weir Mitchell[1] in 1878 when he first clearly described the clinical picture of the condition. He said: "I believe the group of cases now described represent an unrecognised type of spinal or cerebro-spinal disease and that they may be found in the future associated with distinct lesions in definite regions." Lewin and Benda,[2] discussing a series of cases collected from various writers, consider that erythromelalgia was not a disease *sui generis* but generally a symptom of definite disease of the central nervous system or of functional disease. Auerbach and Edinger[3] last year published a case of tabes in which erythromelalgia confined to the right foot was a conspicuous symptom. After death degeneration of the posterior roots of the lower lumbar and sacral nerves

almost confined to the right side was found. The spinal ganglia and peripheral nerves were thoroughly examined and found to be normal. The degeneration principally affected, in the spinal cord, the tract lying close to the septum on the right side usually described as rising from the upper sacral roots, which were in this case found totally degenerated; the erythromelalgia was confined to the skin areas supplied by the fifth lumbar and first and second sacral roots. Very few cases of erythromelalgia have been reported in this country and it is not recognised as a condition occurring in spinal disease. There seems reason to believe, however, that the condition would be found not infrequently if looked for and may be of great importance in the diagnosis and prognosis of nervous disease.

Erythromelalgia is characterised by acute vaso-dilatation over a definite area of the body. The skin assumes in marked cases an intense purple-red colour, swells a little and becomes tense and shiny. The superficial veins of the affected region stand out prominently. The skin can be felt to pulsate and the surface temperature is raised often as much as two degrees above that in the non-affected regions. Severe burning pain, often described as being like a strong galvanic current applied to the skin, accompanies the redness. When the affected area is analgesic patients experience intense tingling, but no pain. The attacks may appear spontaneously or may be induced by exertion, warmth, or emotion. The effect of position upon the affected region is remarkable, so that when the foot is affected an attack may be often brought on at once by merely allowing the foot to hang down, and during the attack that position always increases the pain and the vascular phenomena. Many cases have been reported in which patients have been entirely unable to stand on account of the pain the erect position produced. Elevation of the affected part always causes the pain and the state of vaso-dilatation to pass off so long as the elevated position is maintained. During the attack the application of warmth to the part affected increases the pain and cold greatly relieves it. The surface temperature of the erythromelalgic skin is raised when the part is dependent sometimes to a remarkable degree and lowered when the part is raised. In a normal limb the reverse is the rule. This effect of position upon the vaso-motor state and temperature of the limb is highly characteristic of erythromelalgia. Tender points are frequently observed over the affected area and hyperæsthesia is common. Localised sweating of the skin during the attack is common and thinning of the skin, with brittle, reeded nails, sometimes occurs. The distribution of erythromelalgia is generally peripheral upon the limbs. Rarely the face and trunk have been affected. The lower extremities are more frequently affected than the upper; the distribution is not that of nerve-root or nerve-trunk—it is often limited by a sharply marked circular line round the limb. As a rule the limbs are affected symmetrically, although frequently one limb is affected before the other. The condition shows a marked tendency to spread until the whole distal part of the limb is affected. The duration of the attacks varies from half an hour to several weeks[4]; it is usually three or four hours. Hæmoglobinuria has not been found associated with the condition. The patients rarely suffer with chilblains or "dead fingers."

I have observed ten cases showing erythromelalgia in different degrees of severity at the National Hospital for the Paralysed and Epileptic during the last six months and I am much indebted to my chiefs—Dr. Jackson, Dr. Buzzard, Dr. Bastian, Sir William Gowers, Dr. Tooth, and Dr. Colman—for permission to publish the following notes.

CASE 1. *Disseminated sclerosis.*—The patient was a woman, aged twenty-nine years, of healthy appearance. The symptoms of spinal cord disease began nine years before admission. On admission examination revealed pallor of both optic discs, slight weakness of both external recti, diplopia, and slight nystagmus. There was no speech defect. There were slight intention tremor of the hands, loss of control of both sphincters, severe spastic paraplegia with some ataxy of the legs, inability to stand, double rectus and double foot clonus, no sensory disturbance, and some hyperæsthesia of the feet. Seven years before admission she noticed attacks of burning pain in both feet associated with great redness and heat. These occurred spontaneously and whenever the feet became hot. The attacks lasted about three hours and were at once relieved during that time by the recumbent posture, but the pain and redness returned when she put her feet to the ground. A year later the feet gradually became permanently red and the dependent position of the legs became an active factor in producing the attacks. Sixteen months before admission the feet always became purple and painful when allowed to hang down. The redness, up to this time confined to the feet, extended as high as the knees. The feet swelled during the attacks and sometimes subcuticular hæmorrhages occurred. The feet and legs were then constantly red in whatever position they were placed. Since this time up to her admission the attacks continued, but less frequently than before. As she lay in bed the legs showed a red blush limited sharply above by a circular line just above either knee, which below the middle of the calves changed to a deep purple colour and over the feet showed some mottling. The feet were cold to the touch and pressure produced an intensely white mark which slowly became red. When the feet were hung over the edge of the bed or when she assumed the upright posture they became of a much brighter purple colour and became very hot to the touch. The skin became tense and shiny and the feet swelled but did not pit on pressure. The veins stood out and the whole foot and leg below the knee could be felt to throb. She had intense burning pain limited to the region of redness. A surface thermometer was applied to the dorsum of each foot for ten minutes, the feet being raised above the level of the body. A second application was made for a similar period, the legs being allowed to hang over the edge of the bed. The temperature in the raised position was as follows: in the right foot 94·8° F., in the left foot 94·6°; in the dependent position, right foot, 96°, left foot, 95·8°; the difference being—in the right foot, 1·2°, and in the left foot, 1·2°. On two occasions while she was under my care I was called to this patient in the night and found her crying out with pain in the legs, which presented a condition of erythromelalgia even more severe than that just described as the result of hanging the legs down and with similar distribution. She was relieved by the application of cold and by bandaging the feet tightly with Martin's bandage.

In this case the following points are of interest. The pain and vaso-motor disturbance always appeared simultaneously. The attacks were at first spontaneous only but subsequently they were often brought on by the dependent position of the lower extremities and lastly always induced by the dependent position. When this patient was wearing tightly applied Martin's bandages from the foot to the knee she could sit with the legs down in comparative comfort. The slow supervention of a gradually deepening permanent vaso-motor palsy, uninfluenced by the position of elevation of the limbs, and occurrence of acute spontaneous vaso-motor disturbance in its area of distribution may have a most important bearing on the pathology of erythromelalgia.

CASE 2. *Disseminated sclerosis.*—The patient was a woman, aged forty years, delicate-looking and sparely nourished. Ten years before admission she had transient amblyopia of the left eye. Her present symptoms dated from a chill seven months before admission. At the time of admission there were pallor of both optic discs, concentric contraction of both visual fields and slight nystagmus on extreme lateral deviation. Speech and the upper extremities were normal; the lower extremities were very weak in all movements. There was marked wasting of the muscles in the left thigh and calf; dorsiflexion of either ankle was impossible; the gait was peculiar and strongly suggestive of functional disease. There was loss of sense of position below the hips. There was no anæsthesia. The sphincters were natural, the knee-jerks were difficult to elicit, and the plantar reflexes were very faint. Four months before admission she noticed sudden burning pain in the feet as she was walking. The pain lasted some time and occurred on several occasions. Soon afterwards similar pain was noticed at night and she thought a very hot foot-warmer was in the bed and asked to have it removed. These attacks frequently recurred. A month before admission the feet became red and painful when she stood up. The recumbent position at once caused the pain and redness to disappear, as did the application of cold. As she lay in bed the feet presented a natural appearance. Directly the feet were lowered typical erythromelalgia was seen in either foot, limited by a sharply marked circular line just

[4] Two cases with attacks of very long duration are reported by Cristiani, La Riforma Medica, Torino, 1894, vol. iv., p. 4.

Digitized by Google

above the malleoli. At times for days together no vaso-motor phenomena appeared when the patient stood up and at other times the erythromelalgia would appear in one foot only. When the feet were warm to the touch as she lay in bed the vascular phenomena always appeared if the legs were allowed to hang down or if a ligature were tied round the calves. There was no persistent vaso-motor palsy. The soles of the feet and the calves were very tender on pressure. There were no trophic changes. This patient had several spontaneous attacks when in the recumbent position. Subsequently she developed complete paraplegia, reflex flexor spasm, complete anæsthesia below the knees, and loss of control of the sphincters with cystitis. She became completely bedridden and since then the vaso-motor disturbances have not again appeared.

The aspect of this case at first was strongly suggestive of functional disease. The presence of erythromelalgia at that time was much in favour of organic disease. The diagnosis of disseminated sclerosis was fully confirmed by the subsequent course of the illness.

CASE 3. *Disseminated sclerosis.*—The patient was a woman, aged twenty years. Her symptoms began three years ago. When admitted to hospital she had slight weakness of the right arm with marked incoördination and intention tremor, slight incoördination and tremor in the left hand, spastic paraplegia with marked ataxy, no anæsthesia, and loss of control of the sphincters. The knee-jerks were exaggerated, there was double foot clonus, and the triceps and supinator jerks were absent. While in hospital she first noticed severe attacks of burning pain in both feet when they became warm in bed at night, lasting a variable time from a few minutes to several hours. There was well-marked erythromelalgia over both feet limited above by a circular line just above the ankle, that on the right foot being more intense. During the attacks the dependent position of the feet increased all the symptoms and raising the limbs above the level of the body alleviated them, but the dependent position did not seem to be a factor in inducing the attacks. A month after the appearance of the erythromelalgia a condition of permanent vaso-dilatation made its appearance over the same area and gradually deepened in intensity as the attacks went on. Nine months later the attacks became much more frequent; she became quite paraplegic. Since this time the vascular disturbances have gradually diminished and have now been absent for some months.

CASE 4. *Disseminated sclerosis.* — This patient was a married woman, aged twenty-nine years. Her illness began after a confinement three years before admission. On admission she had unequal pupils, transient diplopia, spontaneous rotatory nystagmus, and coarse nystagmus on deviation. Speech was halting and there were slight tremor of intent in the upper limbs and marked incoördination and intention tremor of both legs. All movement of the lower extremities was very weak. Romberg's symptom was present. There were no anæsthesia or girdle sensation. There was reflex incontinence of urine. The knee-jerks were exaggerated, R. > L. There was double foot clonus. The skin over the outer side of the left foot, including the two outer toes, not extending on to the soles and extending an inch above the external malleolus, was of a red colour, sharply marked off from the surrounding skin, which was pale. The whole left leg below the knee showed a curious *tache* not unlike urticaria scripta.[5] At times and for periods of twelve hours together when she stood up the red area above described assumed a condition of typical erythromelalgia and she had severe pricking pain confined to that area. Alteration of position had the usual effect upon the redness and pain. At other times the erythromelalgia could not be brought on by prolonged exertion or by immersing the feet in hot water or by placing a ligature round the limb. The soles of the feet and calves were tender to pressure. She had attacks of severe burning pain in both feet at night, but this occurred only twice while she was under my care and on neither occasion were the feet seen.

The noteworthy features of this case are the distribution of the permanent vaso-dilatation and the *tache*.

CASE 5. *Neurasthenia with (?) disseminated sclerosis.*—This patient was a single woman, aged thirty-four years. Six years before admission she had double oöphorectomy performed for the relief of dysmenorrhœa. The operation was followed by severe neurasthenia. For two years she had been unable to walk or sit up and for the last year there had been slight trouble with micturition. All movements of the limbs were executed feebly and languidly. There was no wasting, tremor or ataxy. She could not sit up in bed and when she attempted to stand she fell "all of a heap." There was distinct left hemianæsthesia and occasional slight delay in micturition. The plantar reflexes were absent and the knee-jerks were brisk. There was left foot clonus. The nails of the fingers and toes were thin, reeded, and brittle; the skin of the hands and feet was soft and thin and perspired profusely. Three years ago she began to have attacks of pain in the hands and feet; sometimes in the hands only. They occurred at night, lasting some hours, and she got into the habit of sleeping with the hands above her head to lessen the pain. Soon after this time she noticed that the dependent position of the limbs brought the attacks on and she had been unable to put her feet to the ground for weeks together on account of the pain. The attacks were accompanied by excessive tenderness and profuse sweating of the hands and feet. They were much better in the winter than in the summer; often in the winter she had gone months without any attack. On examining this patient one morning I discovered a slight degree of erythromelalgia in the left foot. This had passed off by the following day and for the next month she showed no sign of the condition, though I repeatedly tried to induce it. At the end of this time I was called to her one morning and found her crying out with pain, a severe condition of erythromelalgia being present, limited in the hands by a line round the forearm an inch above the wrist and in the feet by a circular line just above the ankle. The left foot was more affected than the right. The hands and feet were perspiring profusely and she complained of a pain as if she were being burnt in the balls of the fingers and toes. Pressure over the heads of the metacarpal and metatarsal bones on the ventral aspect gave great pain. The effect of position and of the application of cold was typical. The following was the surface temperature taken on the dorsum of each hand: hands straight up in the air—right 88·4° F., left 88·6°; hands hanging down—right 90·6°, left 90·8°; the difference being, right 2·2°, left 2·2°. During the remainder of her stay in the hospital these phenomena appeared unvaryingly when the feet and hands were dependent and some degree of vaso-dilatation was constantly present over the areas affected by the erythromelalgia. In this case the erythromelalgia was the earliest organic symptom to make its appearance and together with the sphincter trouble and foot clonus of later onset suggest strongly the presence of organic spinal disease. In connexion with the oöphorectomy it is interesting to note that in several published cases in males erythromelalgia has been associated with aspermatism.

CASE 6. *Disseminated sclerosis.*—The patient was a woman, aged thirty years. Her symptoms had been present for five years. On admission she had concentric contraction of both visual fields, slight left ptosis, some weakness of the right external rectus, nystagmus, slight tremor on execution of fine movements in the upper extremities, severe spastic paraplegia with ataxy, less of muscular sense in the lower limbs, partial anæsthesia of the legs, and loss of control of the bladder; the knee-jerks were exaggerated and there was double foot clonus. For the last two years she had had attacks of a burning and uncomfortable but not painful sensation in the neck and ears, associated with great redness and heat of the skin. The attacks always occurred when she was recumbent and were brought on by motion. The skin over the whole neck as low as the clavicle and over the whole head, excluding the area of distribution of the fifth nerve, during these attacks became of a red colour, very hot and slightly swollen. The attacks lasted about half an hour.[6]

CASE 7. *Tabes dorsalis.*—The patient was a man, aged thirty-one years. He had had syphilis nine years ago. The symptoms had been present for two years. He had unequal Argyll-Robertson pupils, incoördination of movements of the upper extremities and complete loss of muscular sense in the three ulnar fingers of both hands, tactile anæsthesia and partial analgesia below the sixth cervical root distribution, absolute analgesia below the third lumbar root distribution, lightning pains, girdle sensation, absolute loss of muscular

[5] A similar condition occurring in association with erythromelalgia is reported by Senator, Berliner Klinische Wochenschrift 1892, Band xxix., pp. 1125-9.

[6] A case of tabes with similar distributio is reported by Benda, Berliner Klinische Wochenschrift, 1894, Ba d xxxi., pp. 53, 89, 117 and 14

Digitized by Google

sense in the legs, Romberg's sign, and absent knee-jerks; there was no sphincter trouble. He had noticed for two months that the feet and legs as high as the knee became red, swelled and tingled all over when he tried to walk or when he was sitting with legs down and that sometimes they became very red and tingled when he was in bed. There was a typical condition of erythromelalgia over both lower extremities, gradually becoming less marked from below upwards and ceasing just above the knee. This varied much from day to day, at times being more severe, at others hardly noticeable or absent. Surface thermometry gave the following results: legs horizontal — right foot 85·6° F., left foot 89°; legs dependent — right foot 86·6°, left foot 90°; the difference being, right foot 1°, left foot 1°. (A Hicks' thermometer was applied to the dorsum of the foot for ten minutes in each case.) There were no trophic changes, no sweating, no tender points, and no persistent vaso-motor palsy. Whilst under observation he had severe gastric crises; during several of them attacks of erythromelalgia in both hands limited sharply at the wrists were seen, but the attacks were accompanied by tingling and not by pain, the absence of which in both hands and feet during the vascular disturbance is to be explained by the fact that both regions were analgesic.

CASE 8. *Tabes dorsalis.*—The patient was a man, aged fifty-two years. He had had syphilis twenty-five years ago and had had two attacks of lead colic. On admission he had unequal Argyll-Robertson pupils, incoördination and loss of muscular sense in the arms and legs, Romberg's sign, marked anæsthesia and analgesia below the sixth cervical root distribution (the anæsthesia splitting the middle finger), which become almost absolute below the tenth dorsal level; lightning pains, girdle sensation, severe gastric crises, and delayed micturition. The knee, wrist, and elbow jerks were absent. There was alopecia over the fifth lumbar and first sacral root areas. The skin over the feet was thin and shiny and the nails were brittle and reeded. A history of erythromelalgia was carefully inquired for with negative result. After he had been under observation a month one morning he had an attack of severe gastric pain and went to bed. Immediately afterwards both hands assumed a deep purple colour and felt as if they would burst. They tingled all over, the veins stood out, and the whole hands throbbed. The skin became very tense and swelled slightly. The redness was sharply limited above by the flexure of the wrist on the radial side and extended for 2 in. above the wrist on the ulnar side. It was quite symmetrical. Raising the hands above the head caused the redness and tingling to disappear; lowering the hands caused the symptoms to reappear and become intense. The following are the surface temperatures. Hands raised above the head—right 89·5° F., left 89·5°; hands hanging vertically—right 92·5°, left 92·5°; the differences being, right 3°, left 3°. The attack lasted three hours and for six hours after it had passed off some degree of erythromelalgia could be produced by allowing the hands to hang down. Up to the present time this patient has had no further attack. In this case, as in the last, the vascular disturbance was situated in an analgesic region and tingling appeared in the place of pain. In both cases the vascular and gastric crises appeared simultaneously.

CASE 9. *Myelitis.*—The patient was a man, aged thirty-five years. His symptoms began gradually in February, 1896. When this note was made he had severe spastic paraplegia with ataxy and reflex spasms, partial loss of sensibility from the xiphoid cartilage downwards and delay in micturition; the knee-jerks were exaggerated and there was double foot clonus. At Christmas, 1897, he first noticed attacks of burning pain in the feet associated with redness and heat. The attack occurred almost every night and he constantly required injections of morphia to ease the pain. There was a condition of marked erythromelalgia over both feet limited sharply at the middle of the calf. It varied greatly in degree at different times. Subsequently this patient recovered such power in the legs as to enable him to walk. The attacks still occur when he walks about much but are much less severe than formerly.

CASE 10. *Traumatic neurasthenia.*—The patient was a man, aged twenty-five years. His symptoms followed a severe fall on to his back fourteen weeks before admission. On admission all movements of the lower limbs were performed feebly and with much coarse tremor; there was no rigidity and no wasting. He trembled all over when he tried to walk and frequently dropped on his knees. His gait was typically functional. There was intense tenderness over the last lumbar spine but no abnormality in the spine or pelvis. There was absolute analgesia and diminished tactile sensibility over the lower extremities below Poupart's ligament on either side. He had slight difficulty in starting the act of micturition. The knee-jerks were exaggerated and there was double foot clonus. While in the hospital this patient for the period of a fortnight had several attacks of erythromelalgia of slight degree, the distribution being from the knee downwards and quite symmetrical on the two sides. The redness was not sharply limited above but faded off gradually into the normal skin. The attacks, which occurred several times a day and lasted about two hours, became slighter and disappeared at the end of a fortnight. I have since heard that they have returned.

This case was without doubt chiefly one of traumatic neurasthenia, but the existence of slight sphincter trouble and persistent foot clonus suggested that there was some lesion of the spinal cord. The occurrence of erythromelalgia strongly supported the probability of this.

The occurrence of these cases within a short period of time argues that erythromelalgia is not a rare symptom of spinal cord disease. It has without doubt frequently been overlooked. In the absence of symptoms pointing to the disease of the nervous system erythromelalgia has been investigated as an entity and the earlier literature on the subject relates chiefly to "idiopathic" cases. Lannois[7] in a collection of cases published before 1880 states that nervous symptoms are only rarely coincident. The prevailing opinion at the present time among German writers is the opposite extreme to this. When a case presents as one of definite disease of the nervous system, erythromelalgia, if it occur, may not be recognised as such and may be simply noted as "vaso-motor paralysis," the accompanying sensations being set down to some of the many subjective peripheral sensations occurring in spinal cord lesions. One of its most characteristic symptoms—pain—may be absent if there be analgesia, as was the case in the two tabetic patients cited. Again, the variability of the occurrence of the symptoms—often absent for long periods together, especially in patients who are confined to bed—renders it easy to be overlooked. I would suggest that if the symptom be looked for with a knowledge of the peculiarities distinguishing it from other forms of vaso-motor paralysis it will be found not uncommonly in disease of the spinal cord.

In several of my cases there occurred at first only spontaneous attacks; afterwards the conditions became frequently induced by the dependent posture, and later a condition of permanent vaso-motor palsy of greater or less degree made its appearance; the attacks meanwhile continuing. This sequence suggests an irritative lesion of nerve structures governing the blood-vessels being the cause of the vascular crises and of the progress of this irritative lesion to a partially destructive lesion being the cause of the persistent vaso-motor palsy, these phenomena in vaso-motor nerve elements being parallel with pain followed by anæsthesia in sensory nerve elements and with spasm followed by motor paralysis in motor elements. Weir Mitchell used the term "vascular storm" in reference to this condition and the term "vascular crisis" would, I think, be very apt, occurring as it does in tabes associated with gastric and other sensory "crises." Probably the same fundamental pathological processes underlie both sensory and vascular crises. In all my cases the vascular change was never preceded by the sensory disturbance, but either preceded it or the two appeared simultaneously. It seemed as if the sensory disturbance was a local result of the altered vascular condition of the part. I would lay stress on the fact that erythromelalgia may be the first symptom of organic disease of the cord and may be of great value in diagnosis and especially valuable in the differential diagnosis between functional disease and disseminated sclerosis.

DRAINS AT BODMIN.—At the meeting of the Bodmin (Cornwall) Rural District Council held on July 30th a complaint was made of an open drain at Port Isaac, whereupon a member remarked that personally he did not believe in drains, and added that there was no plague in Bombay before drains were made. Eventually it was decided to instruct the police to report persons throwing slops into the drain.

VITALITY:
AN APPEAL, AN APOLOGY, AND A CHALLENGE ADDRESSED TO BROTHER PRACTITIONERS.

BY
LIONEL S. BEALE.

BIOPLASM.

(Continued from page 144, July 16th.)

ESPECIALLY in warm-blooded animals bioplasm loses its characters soon after death. It becomes liquefied, there being no doubt a minute coagulum at the moment which soon undergoes further changes. The fluid which constitutes the greater part soon permeates the tissues around and the water and dissolved constituents are diffused through the adjacent textures, which, of course, become flaccid and lose the firmness and resilience characteristic of them in the living organism and for a short time after death. Generally, the constructive and formative agency of bioplasm deteriorates if the bioplasm lives too fast—if the rate at which nutrition and multiplication proceed in the normal state of health is much exceeded—and if this increased rate of living does not soon cease all formative and constructive power is entirely lost, the rate of multiplication increases, and such is the intensity of the nutritive process that the living particles acquire yet increased powers of multiplication and may live at the expense of and destroy the very tissues which had been produced by the bioplasm from which they also traced their descent.

This same process of rapid growth and increased multiplication in low simple forms of life results in mere increase in numbers, though even in this case there may be some change —some deterioration in vital power. But generally in the case of the lower microscopic fungi and allied organisms favourable external conditions and plenty of nutrient matter cause greatly increased and more rapid multiplication only.

But in the case of man and many of the higher animals if the bioplasm of the tissues grows and multiplies at a rate which considerably exceeds that which is normal, as occurs in "inflammation and fever," it very soon loses its tendency to produce bioplasts having normal formative power and soon "pus corpuscles" may result. Thus the vital biological process is soon replaced by a vital pathological process. So numerous are the bioplasts produced that they may fill the surrounding spaces amongst the tissues. Such phenomena are of great interest to us and illustrate principles in action through nature that deserve more consideration in pathology and medicine than they have yet received. The living descendants of normal bioplasts which had living formative capacity are represented by "pus corpuscles" injurious to the organism in which they originated. Evanescent and short-lived, they soon become a prey to bacteria and other low forms of life and are lost.

When, on the other hand, the bioplasm of our tissues lives too slowly a low kind of formed material is produced which in many characters departs from the normal standard. This may gradually accumulate so as to interfere with action and in many cases with the removal of the substances formed during action; and, again, a pathological change of a kind very different from normal biological changes and also from those resulting from living too fast is the consequence, but slow deterioration and incapacity succeed.

In the lower forms of life, as in the case of the microscopic fungi, when the conditions are unfavourable and nutrition and multiplication proceed too slowly the bioplasm ceases to grow and much is converted into hard formed matter by which the speck of bioplasm that is left is protected from injurious influences and is thus enabled to live through a long continuance of adverse conditions. Not only so, but the living particle, however minute it may be, during its comparatively passive state seems to acquire and accumulate vast vital power of its low simple kind, for after living apparently dormant for months, when favourable conditions of temperature, moisture, &c., are established, the thick protective covering is soon softened and permeated by nutrient matter. The enclosed bioplasm soon increases, portions of it burst through the walls which enclosed it, pass out at any weak spots and soon gain the outside, when at once it lives freely, increases and multiplies exceedingly and in a wonderfully short time, and then growth and multiplication proceed in the usual manner.

Generally, the production of bioplasts which are to take part in the production of bioplasts which are eventually concerned in the formation of highly complex tissue and various formed substances, is a slow process. Vital phenomena requiring but a very small quantity of matter proceed in the bioplasm of every bud during a long time in the dark and cold part of the year, when as we say vegetation is at rest or asleep; but all this time the bioplasm is gaining in power—vital power is as it were accumulating or concentrating. The early vital changes, and the arrangement of the bioplasts of the plant bud from which the tissues of leaves, flowers, and fruit are eventually evolved, is a slow operation indeed compared with the growth of these; until the development of the bioplasts and their orderly arrangement are slowly completed active growth does not begin.

The evolution and development of the active part of the ovum and seed are slower and still more wonderful as regards the concentration of developmental and formative power not to be actively manifested until a considerable period of time has passed, the bioplasm of course being in living state and probably undergoing important changes during the whole time in preparation for the wonderful and often rapid increase and growth with which all are familiar.

According to the notions of our time we might say that we may hold alive in the palm of the hand the potential future forest. The potential part of the germ of animals and man having its wonderful powers of evolving many kinds of tissues and organs of great complexity and perfect action, is so minute that probably that of the largest organism that ever lived on earth or in the water was considerably less than the head of the smallest pin. Verily, it is indeed difficult to understand how anyone can regard matter and its physico-chemical changes as all in all, and almost ignore the existence and operation of vitality that governs, directs, and determines the changes which the matter is to undergo.

That throughout living nature, from the time of the first appearance of life, all arrangements and actions of tissue, however complicated or inexplicable, have been a direct consequence of the influence of the vital power of the bioplasm and have resulted from changes before the formed material was produced and manifested its characters, may be regarded as certain. The facts prevent the acceptance of any other conclusion. Surrounding conditions undoubtedly exert a modifying influence, and in more than in one or two characteristics, but are incompetent to give rise to any vital changes whatever. They may check, stop, or, on the other hand, may facilitate the activity of vital phenomena. They may interfere with the completion of the series of already arranged-for changes. As some would say, external conditions may affect the evolution of an individual, a species or a race, and in many ways; and, on the other hand, may stop and indeed often do stop evolution altogether and put an end to life.

By studying the growth and arrangement of a tissue we may mentally trace the different stages of its formation, as it were backwards, until we reach the colourless, structureless bioplasm in which it originated—nay, when we see impression of its structure we may sometimes decide the general nature of, if we cannot actually identify, the organism from which it was derived, just as from the footmarks upon a slab dug up yesterday after it had been lying buried undisturbed for ages we may feel sure as to the sort of foot which made the impressions at the time of a living world, very different from our life world, and of which but a few traces are still to be seen in a small number of living organisms of the living world of our time, so marvellously different from those referred to of past ages, though in unbroken continuity with it and at least certain forms of its far remote living matter. Not only so, but those familiar with anatomy and the structure of tissues may, from the character of the imprints, form some notion of the characters of the tissues of that primeval foot, of the muscles by which the toes were moved, the tendons by which they were connected with the bones, and the nerves distributed to the tissues. Further, the sort of legs, the body they supported, and even the habits of the creature and many other facts connected with its existence may be surmised. The minute structure of its tissues, the changes which occurred in their formation, the general character of its living matter, are now as certain as that the sun whose rays light our earth at this moment is the same sun that rendered possible those imprints made æons ago, and the reason becomes convinced that long ere those primæval times the same principles prevailed then as regards the vital phenomena of that

Digitized by Google

so-called extinct living world as prevail now, and over all the same Infinite Power that was and is and is to be.

By the careful examination of the complex arrangement of nerve plexuses and networks in many parts of the organism we may form some idea of the movements of the bioplasts at a very early period of development long before a trace of the fibres and nerve trunks was to be discerned. For this purpose it is better to take a small animal than a large one—the little green tree frog, Hyla, a young white mouse, or a bat. The tissues of these animals are delicate but make beautiful specimens, and there is very little indefinite connective tissue to prevent us getting a clear view of the course and arrangement of the delicate nerve fibres in many parts and organs. That specimen showing the spiral arrangement of one of the fibres of a nerve cell from the Hyla figured in my drawings[1] and copied into many works demonstrates several general points connected with the arrangement of nerve fibres of great importance, though very different conclusions have been entertained with regard to the structure and action of such remarkable nerve cells. The fibres—one straight from the central part, the other spiral from the circumference of the body of the cell—may be traced to a point a short distance from the cell where one curves round the other fibre, so that they pursue *opposite directions* in the bundle of fibres with which they run. These and other points are referred to in my paper in the Philosophical Transactions of the Royal Society for 1863, Part II., p. 543.

Another example of the demonstration of a particular fact bearing upon important general questions, occurs in a specimen also from the Hyla in which a delicate nerve fibre can be followed from the fibre connected with it to its distribution on a capillary vessel, and its course may be traced for some distance near the outline of the vessel, which is also distinct. Upon comparing both these specimens with the drawings made on the wood blocks many years ago and afterwards engraved line for line, the correctness of the figures published in 1863 may be confirmed, and I think I am justified in saying that it is not easy to draw conclusions widely different from those I have arrived at concerning the arrangement depicted. These specimens were examined early this year by Dr. Alexander Morison.[2]

Now the facts alluded to do not accord with some of the first principles of nerve distribution and nerve action which are entertained. Both specimens it need scarcely be said have some bearing upon the questions of nerve distribution, nerve ends, and nerve circuits which lie at the root of the problem of nerve action.

Notwithstanding the thousands of miles of type being constantly set up an English biologist has, indeed, very little chance of gaining the attention of the numerous active students of biology of the last decade or two either here or in other parts. I may be permitted to remark with regard to many recent observations concerning the arrangement of nerve cells and nerve fibres that the general conclusions of some good observers appear to be coming rather near to some of those represented in my drawings published about forty years ago. In particular as to the connexion of at least two nerve fibres with every nerve cell, while "apolar" nerve cells seem at last to have been given up. Then the "nerve ends" seem to be gradually extending themselves farther and farther from the "nerve cells," both central and peripheral, and I begin to look forward in hope to the time of still more extensive fibre elongation, and even some day to the admission of nerve circuits, structural continuity between "cells" and fibres everywhere, and uninterrupted tissue communication between all seats of nerve action in distant parts and central nerve cells. I look forward to the exposition of the development of the nerve systems of all organisms which possess them, from structureless bioplasm, and the explanation of the mode of working of every part of the most complex and elaborate nerve tissue arrangements in living nature. Few observers seem to venture to give an opinion on the question of action of the arrangements they describe. The anatomical distribution of the fibres and the general anatomy and distribution of the nerve fibres—indeed, the whole nervous system of man—is gradually being reduced to form and order by dissection, by experiment and microscopical observation, and by careful investigation of various cases of disease, especially where the pathological changes are restricted to particular parts of the peripheral and central portions of the nervous system. But still many first principles remain undetermined and we have yet much to learn concerning the minute structure and action of the simplest central and peripheral nerve arrangement, of the precise action of nerve cells and the origin, nature, and mode of transmission of nerve currents. Criticism in this department to be of value to us must be careful and thorough. So far few attempts have been made to collate the multitudes of observations and views of the many workers and thinkers in this important department of knowledge so very closely connected with a knowledge of human action in health and disease.

I long to go further and think I could climb higher, much higher, and yet not reach the last rung of the strong ladder of observation and demonstration, particularly as regards this arrangement, development and action of nerve fibres and nerve "cells," but for the present forbear, for I fear I have already exhausted the patience of my readers with descriptions of minute anatomical details, their meaning and the manner in which they were produced, though so far I have described only what I have demonstrated and can show to others. The conclusions I have arrived at are, I believe, the only inferences that are reasonable and I believe the evidence to be convincing that all growth, all structure, all formation, are determined by vital action and depend in the whole living world upon vitality. Above all things, I desire that the attention of my readers should for the present be concentrated upon the consideration of this most important question—the existence of vitality as distinctive of the whole living world—peculiar to it and not representing or analogous to anything else in nature. If the conclusions at which I have arrived are wrong, scientific men who differ from me and teach totally different views ought to expose my errors and state the grounds of their objections. As regards all living matter being due to vitality, to the uninterrupted action of vital power operating in everything living, but in the living world only, I submit the following conclusions based upon facts of observation and expressed as clearly and in as few words as possible.

Everything living, the whole living world, past as well as present, was first in the state of colourless structureless living matter—bioplasm.

Some of the lowest forms seem to be structureless during the whole period of life; and all during the earliest stages consist of bioplasm with no discernible formed material or structure.

However complex and elaborate may be the structure of the highest organisms in the fully developed state, all were originally bioplasm or structureless living matter—were evolved from this. Without bioplasm evolution of any kind is impossible.

Every tissue, every structure, every organ is formed from and by the structureless bioplasm, and as far as is known there is no other mode of formation in living organisms.

Bioplasm manifests powers not possessed or exhibited by matter in any other state or under any other known circumstances or conditions—powers of directing, moving, governing, re-arranging material particles — powers of analysis and of preparing for synthesis—powers of preparing for and providing for, and as it were foreseen, future changes and developments. These wonderful powers, as it seems to me, can only be accounted for by attributing them to some power or influence operating in every living particle, but in the living world only—vital power, vitality—Biokraft—"a psychical factor, a factor which no physical research whatever can disclose or identify or get the remotest glimpse of" (Herbert Spencer).[3]

[1] Philosophical Transactions, 1863.

[2] See report of Dr. Alexander Morison's "Morison Lectures," Edinburgh Medical Journal, February, March, April, 1898, p. 228.

[3] Not a little confusion has of late years occurred in the use of the word "psychical," some having extended its meaning and so generalised it until it is made to include those phenomena in all life which distinguish it from all non-life, and which by me have been termed "vital," while by many the word is still restricted to *mental phenomena*. In my view all mental action is "vital" action, but I do not consider all vital action to be "psychical." The "psychical actions" of a bacterium, of a monad, of an entozoon seem hardly admissible unless the word is to be substituted for "vital" in all cases. It has been ingeniously suggested that mental psychical phenomena have a *physical* as well as a *psychical aspect*—a double-faced system, but whether the physical or the psychical begins it, or both begin together, has not been stated.

Digitized by Google

If the ordinary phenomena of life can be explained without postulating any such "psychical factor," why have they not been so explained? What facts or laws, properties, processes, or energies expel vitality from living nature?

Every complex living organism consists of living matter or bioplasm and of formed material or tissue and other formed matters.

Every kind of structureless, colourless living matter in nature is associated with a large proportion of water. In the absence of water life exists not.

The living matter in fully formed organisms is inconspicuous and in specimens prepared by some methods is not seen at all.

Every particle that lives consists of: (*a*) living matter; (*b*) matter that has lived; and (*c*) matter which is about to live—matter about to be taken up by the living matter.

All growth, all formation, all structure and action, depend upon living matter.

Vital power is only imparted to non-living matter when it is infinitely near matter that lives and does not appear to exert any influence upon matter separated only by the very slightest space.

The "nutrient substances" dissolved in a large proportion of water seem to pass into the very centres of the particles of living matter where certain of the constituents are caused to live.

Bioplasm or living matter invariably proceeds from bioplasm that existed already.

Bioplasm cannot, as far as is known, come from the non-living and there is no gradual change from one state to the other.

All vital phenomena are absolutely different from any physical phenomena.

Bioplasm cannot be produced artificially.

It is probable that from the very beginning living matter exhibited the same general characters it exhibits to-day—always was and will be transparent, colourless, structureless, possessing spontaneous vital movements and analytical and formative power.

In all living matter then there is power or capacity of rearrangement of the constituents in a predetermined manner so that special substances and special structures shall result when the matter ceases to live.

I am quite ready to publicly admit mistakes if my observations can be proved wrong, but I have been so many times over the same ground and have examined the corresponding structures and their arrangement and studied their growth and formation in so many different organisms that I cannot believe my general conclusions as to vitality, the nature of growth and formation of tissue, are far from the truth.

I also hold strongly to the general arrangement that I have described of the finest nerve-fibres centrally and peripherally. I have been unable to satisfy myself of the existence anywhere of nerve ends or of central "cells" destitute of fibres or having the one fibre only. And surely by this time we ought to have been able to decide upon many such elementary questions of fact, involving as they do principles of the highest importance, not only to science, but to general knowledge—questions which now have to be referred to even in general education and are perhaps about to be subjects included in "secondary education."

Is it not extraordinary that even during the last half-century many trained scientific minds, notwithstanding the greatly increased advantages we enjoy of being able to penetrate far more deeply into, and to study with greater accuracy, the mysteries of the living world, should, like the natural man of old, have been more interested in the consideration of the tremendous destructive phenomena of the vast and remote non-living rather than in the wonderful if less conspicuous phenomena of living nature—of that living world in which we occupy the most important place, far apart from, if not above, and in a category distinct from, that which includes every other living form? This very small but beautiful and elaborate life-world even now seems to appeal to the general science of our time far less decidedly than the crashing, crushing, terrifying, life-destroying energies of non-living, unapproachable, ineffable immensity.

(To be concluded.)

A CASE OF COMPOUND FRACTURE:

ACUTE TRAUMATIC GANGRENE; AMPUTATION; INJECTION OF ANTISTREPTOCOCCIC SERUM; RECOVERY.

BY W. SOUTHEY WRIGHT, B.A. OXON., M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.

THE following case may, I think, be of interest partly on account of the frightful rapidity with which gangrene came on and partly because of the undoubted efficacy of the antistreptococcic serum in helping to arrest its spread in the stump after removal of the limb.

The patient was a little girl, ten years of age, who fell from a swing near a disused fowl run, sustaining a compound fracture of both bones of the forearm. This happened on May 25th, 1898. I saw her about half an hour after the accident. The wound was not bleeding then although the cloths which had been put on and her clothes were soaked with blood. I washed the wound, through which both bones were projecting, with carbolic lotion and covered it with antiseptic dressings and put the forearm up in back and front splints and left it in the extended and supine position. The patient, a very nervous and excitable child, had borne the necessary manipulations well. On calling next morning I found that she had passed a very bad night. She had been feverish and sometimes delirious. Her temperature was 102° F., her pulse was very quick, and she was wandering. I took off the splints and examined the wound. It was apparently healthy and free from smell and the arm was in fair position. It was again put up antiseptically, but the same night I was called in about 9 o'clock when I found that she had been wandering all day and the bandages were soaked by a thin, bad-smelling discharge; the edges of the wound looked slightly ashy in colour and the wound seemed larger. The bones being very much out of position owing to her restlessness I thought it best to again apply the splints, having first thoroughly cleansed the wound. The next morning (the 27th) I was horrified to find the hand and wrist below the wound quite cold and black and crackling with foul gas, while the whole arm above was swollen and brawny and of a dusky redness which ended in a well-defined raised margin about on a level with the anterior axillary fold. I had the arm immersed in an antiseptic bath and I telegraphed for Mr. Tubby. He arrived in the afternoon and decided on immediate amputation. The difficulty was as to site. The red line was spreading fast and was then close up to the shoulder and it was a question as to whether an amputation through the arm below this point, necessitating as it would the use of flaps which had been already largely invaded, would be preferable to amputation at the shoulder-joint. As the case stood then either seemed a forlorn hope, and while the operation at the shoulder-joint would give a slightly greater amount of healthy tissue for flaps, yet the greater wound surface, the more serious nature of the operation, the infinitely greater deformity should the patient survive, and the very slight hope of survival determined Mr. Tubby to perform an amputation through the arm. We hoped that the tissues of the shoulder would have sufficient vitality to arrest the onward march of the microbes thus cut off from their bases of supply. The limb was removed by the circular method, Dr. Gripper kindly assisting us. We found the tissue slightly healthier than was expected. The artery was quite healthy but there was pus in the vein. The flaps were drawn together loosely to allow of free drainage and the stump was enveloped in iodoform dressings. At Mr. Tubby's suggestion we sent for some antistreptococcic serum, 60 c.c. of which were obtained, and at 12.30 on the same night I went down to inject it. I found the patient, who was taking brandy freely, quiet and rational. The temperature was 99°

Digitized by Google

and the pulse was 108. On examination I found that the red line had advanced since the operation over the point of the shoulder and although perhaps not quite so prominent was yet well defined, while the redness in the axilla had crept down over the ribs. I injected 10 c.c. of the serum into the shoulder just outside the reddened area. On arrival next morning I was delighted to find that this edge had become ill-defined, blotchy, and irregular with rose-coloured processes, some of which extended beyond the point of introduction of the needle, but on the whole the advance seemed broken, while the shoulder itself was much more soft and elastic. The axillary redness was still spreading downwards, so another injection of 10 c.c. was made just within the margin of it. Altogether 50 c.c. of the serum were injected into the affected area and certainly seemed most potent in arresting the spread of the gangrene. No ill effects seemed to follow the injections, an irritable papular rosy rash around the points of insertion of the needle being the only reminder of them, while three or four days after the last injection a rash, consisting of large rose-coloured circular spots, not elevated, and disappearing on pressure, broke out over both buttocks but soon disappeared. The further progress of the case was most favourable, our only anxiety being caused by the passage of clay-coloured stools and bilious urine, but these symptoms soon passed off and no other complications ensued. The temperature never rose above 100° and the only discharge from the wound was a thick mucoid material, inodorous and easily removed, while the wound itself never gave me a moment's anxiety. The patient is now quite well and has no pain in the stump, which is at present quite healed.

The cause of the gangrene we attributed to the bacillus of malignant œdema picked up from the soil, but an examination of some discharge by the Clinical Research Association only revealed the presence of streptococcus longus. I am bound to say, however, that the specimen was sent to them rather late and that then the amount of discharge sent was not enough altogether to exclude the malignant bacillus as the prime cause of the evil. On the other hand, no one who closely observed the effects of the injections could, I think, have failed to notice how very marked they were. Whether the further progress of the gangrene in the stump would have been arrested without their aid it would be difficult to say, but I feel quite convinced that without them there would have been a far greater loss of tissue and that the fair length of stump which the patient now possesses would have been very much less, if not altogether destroyed.

Carshalton.

EXCISION OF THE CÆCUM FOR TUBERCULOUS DISEASE.

BY H. A. LEDIARD, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO THE CUMBERLAND INFIRMARY.

IN July of last year a man was admitted to the Cumberland Infirmary on account of a hard swelling in the right inguinal and hypogastric regions. The age given was sixty-three years, but the appearance suggested at least seventy years. Deafness and hebetude no doubt prevented much historical record beyond the fact that the patient had been ill for eight months and suffered from looseness of the bowels. The swelling was within as well as beneath the parietes and showed no mobility. The first impression was that a malignant tumour was present and no idea of surgical interference was entertained. A rise of temperature, however, occurred and the area of the tumour showed a reddened patch. On August 1st an incision was made and some pus was evacuated and at the same time a piece of the indurated abdominal wall was cut away for examination. The pus appeared to come from the direction of the cæcum, but the incision was made near the middle line and below the umbilicus. The wound was stuffed with gauze and the temperature fell, but in a few days fæcal matter soiled the dressing and it became clear that the tumour was connected with the bowel. Microscopic examination of the piece cut away threw no light upon the nature of the disease. A sinus now led from just below and to the right of the umbilicus towards the anterior superior iliac spine and pus, with occasionally fæcal matter, escaped. Towards the end of the year the patient suffered from chronic bronchitis, mitral disease, emaciation, and great prostration, so much so that further interference was not countenanced. On Dec. 29th the sinus was laid open and traced down to the cæcum, which organ was found adherent all round, and having thick and hard walls. The cæcum was liberated and cut away and the ileum was attached to the wound, whilst the lower end of the colon was closed up. The sinus was scraped out and stitched up. At the completion of the operation I was in doubt as to the nature of the disease, but the extensive ulceration of the mucous membrane of the bowel and the hard and thickened walls suggested malignant disease. Much collapse followed the operation, indeed the removal of the cæcum was somewhat questionable on account of the patient's frailty, but the wound healed easily enough in spite of the mess occasioned by the discharge from the artificial anus. Microscopic examination by experienced hands showed the disease to be tuberculous by reason of the presence of giant cells and areas of caseation. Contrary to expectation the patient lived until Feb. 20th, 1898, but his feeble condition never would have justified an effort to anastomose the small with the large bowel and so close the artificial anus. Nevertheless it would have been better to have tried to do this at the time of excision of the cæcum because the patient exhibited a remarkable tenacity of life even in his feeble condition.

My reason for contributing this brief abstract of the case is through my having seen in THE LANCET[1] reference to the surgical treatment of intestinal tuberculosis. The disease may be more commonly met with than I am aware of, but it is the first case which I have been called upon to treat; on the other hand, cases of cancer of the cæcum have been dealt with by excision by Bruce Clarke, Walter Edmunds, Marmaduke Sheild and others with success, and it is probable that similar results may be recorded in future for tuberculous disease. To others it may be somewhat encouraging to know that a most unpromising subject for surgical measures survived a resection of the cæcum for two months and might have done still better if sufficient courage had been forthcoming to unite the small with the large intestine immediately after resection.

Carlisle.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES OF A CASE OF ANGINA LUDOVICI; OPERATION; RECOVERY.

BY ARTHUR E. PHILIPPS, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a man, aged forty-five years, of temperate habits, consulted me on May 8th, 1898. He gave the following history. During the previous week he suffered from what he described as the "jaws ache," accompanied with occasional stiffness in the submaxillary region on the left side. He was also subject to hot and cold sensations. On May 7th he noticed a swelling in the left submaxillary region and felt that his tongue was being pushed up towards the roof of his mouth. He applied a poultice to the swelling, which increased very rapidly indeed. There was no history of sore-throat. The next evening (the 8th) I was called to see him. There was an indurated brawny swelling filling up the left submaxillary region extending anteriorly to the middle line, posteriorly to about 1 in. beyond the posterior border of the sterno-mastoid, and superiorly to the malar bone, sharply bounded by entirely unaffected tissue. There were parts locally softened and pitting on pressure. Any attempt to open the mouth caused great pain and on this account it was quite impossible to examine the throat. The floor of the mouth consisted of hardened deeply congested tissue and there was a bolster-like swelling round the interior of the lower jaw. The tongue was normal. He

[1] THE LANCET, July 30th, 1898, p. 274.

Digitized by Google

could not swallow anything whatever, being obliged to put milk into his mouth and allow it to run down his throat, and he had great difficulty in speaking. He stated that he was unable to sleep for more than a few minutes at a time. There was no albuminuria. The pulse was 96 and the temperature was normal. On the 9th I saw him early in the morning and found that the swelling had extended in all directions except downwards, almost closing the left eye superiorly and beyond the middle line anteriorly. I anæsthetised the patient with A.C.E. mixture and made a deep incision in the submaxillary region. The anæsthetic was taken very badly. The wound was plugged with carbolic gauze and dressed with hot fomentations. On the 10th, with the aid of an anæsthetist, I made deep incisions in the middle line and along the anterior border of the sterno-mastoid; a thin, dark serum exuded. Both wounds were plugged as before. The patient steadily improved, though suffering from bronchitis following the anæsthetics. On June 1st the median incision and that at the anterior border of the sterno-mastoid had almost healed up, but the tissue around the submaxillary incision had broken down and a large quantity of pus was discharged. A drainage tube was inserted and the wound granulated up. On July 19th the patient felt well, and returned to work.

Fulham, S.W.

A CASE OF MEMBRANOUS TRACHEITIS AND LARYNGITIS WITHOUT THE PRESENCE OF DIPHTHERITIC BACILLI.

BY L. A. GRIMES, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE PHYSICIAN, ST. GEORGE'S HOSPITAL.

A BOY, aged four years and nine months, who was recovering from an attack of measles, was admitted into St. George's Hospital on May 18th, 1898, with marked stridor and great sucking in of the episternal notch and of the lower thorax during inspiration. On examination nothing abnormal was found beyond slight injection of the tonsils. The symptoms becoming rapidly worse and the child being in great distress tracheotomy was performed within half-an-hour of admission. Immediately the tube was inserted a large piece of membrane was coughed up. This membrane was of a greyish-yellow colour and very tough. Dr. Ewart's method of introducing creasoted oil (1 in 20) into the trachea was at once adopted. Five minims every 2 hours had the effect of softening the membrane, thus enabling the child to cough it up more easily and a fit of coughing was usually brought on immediately the oil reached the trachea. After 24 hours the dose was altered to 10 minims every 4 hours. In two days the membrane became quite soft and muco-purulent looking. Bacteriological examinations were made by Dr. Slater on the first day and on three other occasions, but though there were numerous bacilli that of diphtheria was always absent. The membrane became gradually less from day to day and the tube was finally removed on the twelfth day. The child made an uninterrupted recovery and was discharged within the month.

Albert-street, S.W.

A CLINICAL ASPECT OF THE ORIGIN OF TYPHO-MALARIA AND TYPHOID FEVER.

BY OWEN F. PAGET, M.B., B.C. CANTAB.

HAVING been long separated from any centre of learning, the modern view taken by bacteriologists of the biology of the typhoid bacillus is unknown to me, but I would venture to place before the profession some clinical observations made both by others and myself in Western Australia and the Sandwich Islands, together with the deductions arising therefrom.

1. In Western Australia single men and parties went out prospecting, usually taking with them only tinned meats, condensed water, and flour. They necessarily preferred virgin soil and camped as far removed from others as possible. In such a spot they might locate themselves two or three or more months and then develop typho-malaria or typhoid fever. Concisely put, a man starts from a probably typhoid-infected centre well in himself with food supplies almost certainly uninfected; he does not develop the disease until some time after leaving, which negatives the possibility of his carrying the disease with him, but develops the disease at a time when from the nature of his food, his use of patent pills, and the necessity of using local water-supplies—usually mere pools—the three important factors—namely, constipation, catarrh, and an infective bacillus—have been furnished for the development of the disease. 2. In the Sandwich Islands epidemics (not typically typhoidal in character) occur among the labour hands on the plantations characterised by high temperature, diarrhœa, and hæmorrhage from the bowel, and apparently arising through the labourers drinking water from the streams. 3. True typhoid fever occurs both in Western Australia and the Sandwich Islands. 4. In Western Australia cases were far less typical at the commencement than at the close of the typhoid fever season.

The above-mentioned observations have led me to form the following hypothesis: (1) that the typhoid bacillus exists in virgin soil; (2) that the typhoid bacillus requires educating—i.e., transference through a series of hosts before it produces typical typhoid fever; and (3) that so-called typho-malaria is due to an uneducated bacillus. These three hypotheses appear to me to be reasonable, firstly, from their analogy to the biology of the diphtheria bacillus; and secondly, from the excellent results obtained in both diseases by the use of olive oil.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

LONDON HOSPITAL.

TWO CASES OF OVARIOTOMY IN WHICH THE BOWEL WAS TORN; RECOVERY.

(Under the care of Dr. LEWERS.)

PROBABLY the most dangerous complication of the operation of ovariotomy is wounding of the bowel and this most commonly occurs in the separation of adhesions. The presence of an adhesion to a piece of bowel is in itself sometimes sufficient to weaken the bowel wall at the point of attachment, for it tends to limit the action of the muscular fibres in the wall at that spot, and thus may lead to their partial degeneration; as a consequence the wall of the intestine is especially liable to tear when adhesions are being broken through. Nothing but the prompt and skilful suturing of the torn bowel can save the patient's life and those who operate in these cases must be prepared for some of the most difficult complications in abdominal surgery. The uneventful course which such cases may run if the injury is immediately recognised and remedied is well exemplified in the two cases recorded below.

CASE 1.—A married woman, aged twenty-two years, was admitted into the London Hospital under the care of Dr. Lewers on Dec. 18th, 1897, complaining of pain in the right side. She had been married ten months, and four weeks before admission she had a severe pain on the right side of the abdomen which "doubled her up." She at once consulted a medical practitioner who told her to go to bed and ordered poultices to be applied to the abdomen and at first the pain was relieved. Three days later she miscarried, having been six months pregnant. She lost a good deal at the time and continued losing for nearly three weeks after the miscarriage. The pain was still very severe and there was occasional vomiting after food. At the end of three weeks she was able to get up, but the pain returned and she was obliged to take to her bed again, where she remained until she went to the hospital. She has had no shivering fits, but at times she has felt very hot. She had always been delicate and has had scarlet fever and influenza. The catamenia had never been

Digitized by Google

very regular. During her illness the bowels had been very constipated and two days before admission she had an enema. There had been some pain on micturition. In the abdomen there was a swelling rising out of the pelvis; it lay with its long diameter vertically, to the right of the middle line; it measured about 4 in. by 2½ in. The swelling seemed to have a certain amount of mobility and was only slightly tender on palpation. The sound passed seven inches, apparently into the swelling. Bimanually the uterus was fairly moveable and of about the normal size. On admission the temperature was 100·8° F., but by the morning of the second day it had fallen to normal. The patient remained in bed and the tenderness slowly diminished, and the tumour became more defined and more moveable; it was noticeable that the swelling appeared to be close under the anterior abdominal wall. On Jan. 3rd, 1898, there was a little more tenderness over the tumour, but the temperature was normal. On Jan. 15th Dr. Lewers examined the patient under an anæsthetic and found that the swelling could be pushed over to the right but not to the left. The uterus was not enlarged and was quite separate from the tumour; the sound entered 3 in. On Feb. 5th the swelling appeared to be slightly smaller, but otherwise the signs were unchanged. On the 10th the patient was put under the influence of the A. C. E. mixture and a vertical incision 3 in. long was made between the umbilicus and the pubes. The tumour was found to consist of the right ovary which had become converted into a mass as large as a hen's egg, containing pus, some of which escaped on manipulation. The tumour was adherent to the anterior abdominal wall, to a portion of the small intestine and to the vermiform appendix. The adhesions were separated, some being previously ligatured. In freeing some of the adhesions to the bowel a small tear was made through the wall of the intestine; this was closed with fine silk and the peritoneal coat was drawn together over it by Lembert's sutures. Another doubtful opening was similarly covered. The broad ligament and the Fallopian tube were ligatured with stout silk and the ovary and tube were removed. The wound was closed, an iodoform gauze drain being inserted at each end of it, and a dressing was applied. The patient passed a fairly good night after a hypodermic injection of morphine. She vomited several times and complained of much abdominal pain and of thirst. The abdomen was not tender or rigid. The dressings were changed, a little sanious discharge being present. The temperature was normal. The patient steadily improved, the pain disappeared, and the gauze drains were removed on the 16th. On the 24th the stitches were taken out, the wound having completely healed. She left the hospital wearing an abdominal belt on March 15th.

CASE 2.—A married woman, twenty-eight years of age, was admitted into the London Hospital on Feb. 8th, 1898, complaining of dysmenorrhœa and pain on coitus. Her health had on the whole been good. She had small-pox when she was twelve years old. She had been married for five years, but she had not had any children or any miscarriages. The catamenia were regular, but she had usually had a good deal of pain at the commencement of each period. For this she was treated in June, 1897, by a medical man; the cervix was dilated and "electrical treatment" was employed. This was followed by pelvic inflammation and she was laid up for five weeks. On examination a swelling could be felt in the left iliac region, rising about 3 in. above the pubes; it extended as far as, but not beyond, the middle line and it appeared to rise out of the pelvis. The uterus, which was distinct from the tumour, seemed to be very nearly fixed and the sound entered 3 in. The temperature on admission was 100° F., but soon fell to normal. By Feb. 24th the patient's condition had hardly changed; the temperature varied much, rising to 100·5° in the evening and falling to 97·5° in the morning; her general health seemed good. The patient having been anæsthetised, Dr. Lewers made a median incision, 5 in. in length, between the umbilicus and the pubes. The tumour was seen lying in the left iliac region and was of about the size of a fœtal head. It was extensively adherent to the pelvic structures and to the bowel. The mass was gradually separated from surrounding parts, the adhesions being seized with forceps, cut through and ligatured when necessary. Just as the tumour was completely freed and as it was being removed it ruptured and some pus escaped. This was quickly taken up with pads of iodoform gauze and it was then found that the sigmoid flexure had been torn where it had been adherent to the mass. The opening was about $\frac{1}{10}$ in. in diameter. Five silk (Lembert) sutures were inserted. The tumour proved to be a suppurating ovarian cyst; the left Fallopian tube was dilated to the size of the thumb, the walls were thickened and the fimbriated extremity could not be found; the liquid in the tube was blood-stained, but was not pus. The right ovary was slightly enlarged and adherent; this with the right tube was ligatured and removed and the tube was then seen to be dilated to the size of the middle finger and the walls thickened. The ends of two pieces of iodoform gauze were left in the peritoneal cavity, one at the place whence the tumour was enucleated and the other in Douglas's pouch. Five deep and five superficial sutures were inserted in the abdominal wound. Some vomiting occurred after the operation, but the patient slept fairly well, and on the next day the abdominal walls were rigid and only slightly tender, though she complained of much pain. The dressing was changed; there had been a good deal of discharge. The temperature was 98°. During the following night there was much sickness and she had less than an hour's sleep, but the wound looked well. There was slight tenderness at the lower part of the abdomen. By Feb. 27th the vomiting had ceased and milk was taken well. On March 1st the gauze drains were removed; the abdomen was quite free from rigidity. The temperature was 100° and a small piece of gauze was reinserted. The gauze was removed on the 2nd, and though for some days there was much exudation the wound finally closed by the 11th and the stitches were removed on the 15th. She was allowed to get up on the 21st and on the 26th she left the hospital perfectly well.

Remarks by Dr. LEWERS.—A point of some importance in both these cases is that during the greater part of the operation the Trendelenburg position was employed. I think that had it not been for the good view of the parts so obtained the laceration of the intestine might very probably have escaped notice, in the second case more particularly. In Case 1 it will be seen that when the patient was first examined the sound passed 7 in., although the uterus was felt bimanually to be only of about the normal size, and it passed up apparently into the tumour to the right of the umbilicus. On another occasion the sound could only be passed 3 in. At first sight the most probable explanation of such a discrepancy would be that the sound had perforated the uterus. But in the case in question the uterus was carefully inspected at the operation to see if there was any evidence of a perforation having been made and no sign of any such thing was discovered. My belief is therefore that in this case on the first occasion the sound passed along the right Fallopian tube. It is not often that an opportunity of getting fairly conclusive evidence of such an occurrence is afforded and no doubt in many cases where it has been supposed to have happened the explanation is that the sound has perforated the uterus. In the present instance the examination of the uterus during the operation showed conclusively that no such perforation had occurred, while, on the other hand, the right Fallopian tube could be traced from the uterus up to the situation of the tumour, the highest point of which was to the right of the umbilicus. The purely abdominal position of an ovarian tumour of only the size of a hen's egg is no doubt accounted for by it having become inflamed and adherent to the abdominal wall when it had been carried up to its position in the abdomen by the pregnant uterus. The patient had miscarried at the sixth month some three weeks before her admission to the hospital.

ANCOATS HOSPITAL, MANCHESTER.

A CASE OF RICHTER'S HERNIA; SLOUGHING OF BOWEL; SUTURE; RECOVERY.

(Under the care of Mr. STANMORE BISHOP.)

RICHTER'S hernia or partial enterocele was for a long time confused with Littré's hernia, or a hernia of a Meckel's diverticulum. The symptoms which may accompany a partial enterocele may vary within very wide limits. In some cases they are very severe, the vomiting is incessant and a fatal result follows within a short space of time; while in others no signs of interference with the lumen of the bowel are present, and there may be no suspicion of anything wrong until perforation occurs. These differences are probably to be explained by the varying extent of circumference of the bowel included within the constricting ring.

Digitized by Google

In the more serious cases nearly the whole of the circumference of the piece of bowel is involved, and as at the same time the gut is sharply bent, the symptoms are severe; but if only a small proportion of the intestinal wall is nipped, there is very little interference with the lumen and the passage onwards of the intestinal contents, and as a result no vomiting may occur.

A man, aged forty-seven years, was admitted into Ancoats Hospital on Nov. 15th, 1897, for swelling of the scrotum. He had had no previous illness and had no idea of the cause of his present condition. He believed that he must have had a "strain," but remembered no special occasion. Seven years ago he first felt pain in the abdomen and recollected the occurrence of some swelling in the right inguinal region, and for this he wore a truss for three or four years. Since that time he had worn nothing and although having vague pains from time to time he had never been obliged to leave his work. On Nov. 8th, 1897, he had sudden pain, accompanied by great enlargement of the right scrotum. On the 15th, having tried fomentations and poultices in the meantime, he sent for a surgeon, who attempted taxis, and failing sent him to the hospital. He said that the bowels acted during this week but not every day. There had been nausea but no vomiting. When admitted his scrotum was of the size of a Rugby football. Taxis was again tried by Dr. Hartley, the house surgeon, who succeeded in reducing the swelling considerably but not completely. The sensation on taxis was that of reduction of a hernia, the last returned portion passing in with a "slip." On the day of admission the right side of the scrotum was tense, dark in colour, and of the size of a cocoanut. The patient was apathetic; this mental condition increased until after the operation. On the next day (Nov. 16th) a large black slough was found at the lower extremity of the scrotum extending upwards posteriorly. This was offensive in smell and crackled under pressure. On the 17th it gave way and thin fæces escaped. The scrotum was covered by a boric poultice, which was frequently renewed, and by the 25th the necrosed tissue was all removed. Fæces meanwhile escaped freely through the gap and the patient became more and more apathetic. The temperature during this time was very irregular, varying from normal to 100° F.

On Nov. 26th an incision was made through healthy tissues parallel to and 1 in. inside the right anterior superior spine. It opened into a cavity at the base of the scrotum and one continuous with the interior of the right side of the scrotum; both of these cavites contained fæces and were lined by granulation tissue. There was no trace of cord or testis unless these were represented by some strands of whitish fibrous tissue. Above and in the situation of the internal inguinal ring was a gaping opening in the extremity of a loop of intestine with projecting folds of mucous membrane. This opening represented the end of the descending limb, which lay vertically, and from it fæces could be seen escaping. Below and internal was a much smaller opening lying transversely to the former, the end of the distal limb. The two were continuous behind, but in front there was a gap 2 in. wide. An attempt was made to introduce a medium-sized Allingham's tube, but owing to the angle at which the two openings lay this was impossible without freeing the gut from its attachments to the tissues around, which seemed inadvisable, so the two were united by silk mattress sutures which were so applied as to bring the serous surfaces together. A second continuous silk suture was superimposed. The cavity of the scrotum was then laid open and the granulation tissue was removed with a sharp spoon. The raw surfaces were united by sutures, a drainage-tube being left at the lower end. At the upper part of the incision a Mikulicz gauze drain was placed, the deeper part being in contact with the re-united intestine. The wound was dressed on the 28th and 30th. On Dec. 1st the stitches were removed. The temperature had never been above normal. There had been no escape of fæces. The scrotum looked healthy. The tube was shortened and the gauze was removed. The united bowel could just be seen at the deepest point of the upper wound, which was quickly closing up. Urine had been passed regularly without requiring the catheter. For the first two nights 20 minims of nepenthe were required. The patient was much brighter and more sensible. On the 2nd some fæcal matter escaped from the upper wound. This continued and on the 3rd the fæcal discharge was large in amount, but the fæces were thin and unformed. On the 4th the drainage-tube was removed from the scrotum. The fæcal discharge was much less; the scrotal wound had opened up somewhat, but there was no swelling. The bowels acted regularly *per anum* with pulvis glycyrrhizæ compositus. The cavity was well washed out with boric lotion and kept as clean and as dry as possible. On the 5th the fæcal discharge ceased and the opening in the bowel had evidently closed by the rapidly growing granulation tissue. The temperature remained uniformly below normal. From this date to the 12th there was no fæcal discharge and on the 12th the bowel was not visible. The inguinal wound was rapidly closing and the scrotum was much shrunken, the wound being almost healed. He took food well and was cheerful and lively. Both wounds were dressed with iodoform gauze. The bowels acted regularly. On Jan. 8th, 1898, he was discharged well. The inguinal and scrotal wounds had rapidly filled up and no further leakage took place, but he was kept in the hospital partly to ensure safety and partly in order to feed him up. His weight steadily increased from 7 st. 2 lb. on Dec. 18th when he was first weighed to 7 st. 10 lb. when he was discharged.

Remarks by Mr. STANMORE BISHOP.—Three points in this case seem noteworthy. It was evident from the condition found at the time of operation that this had been a Richter's hernia—that is, the strangulated portion of gut which had been compressed with sufficient force to cause sphacelation had not included the entire lumen but only the apex of the involved loop. This has always been considered the most fatal form of hernia, yielding the most pronounced symptoms. In this case, however, the whole process appears to have been gone through without to any great extent producing any constitutional disturbance, since it seems evident that the gut must have yielded on Nov. 8th—the day when he first complained of severe pain and of sudden great enlargement of the scrotum. Sufficient local plastic peritonitis was set up around to block off perfectly the peritoneal cavity and yet no absolute obstruction or even vomiting was produced. The second point is the curiously false impression given as to the result of taxis. The third is the apparently total destruction of the testis. No satisfactory history could be obtained which would show in what manner this came about. Nothing which in any way resembled a testis escaped from the scrotum after its sloughing, yet at the operation nothing but a large cavity lined with granulations and filled with fæces was to be seen

---

A STATUE AND A BUST OF MORGAGNI.—The following account of Morgagni's statue at Forli and his bust at Bologna is taken from an article in the *Gazzetta degli Ospedali* of July 14th. The medical school of St. Thomas's Hospital being desirous of obtaining a bust of Morgagni, an English committee, of which Mr. Shattock was chairman, entered into communication with the Italian medical men present at the Moscow Congress in August, 1897, and they on returning to Italy appointed a committee, with Dr. Soffiantini as its chairman, in order to take steps for the making of a bust on the model of the statue at Forli. This statue stands in the principal court of the Palazzo degli Studi at Forli, was unveiled on May 27th, 1875—that is, a hundred and four years after Morgagni's death at Padua—and was the work of Salvino Salvini, professor of sculpture at Bologna. It was erected at the instance of Camillo Versari, a fellow citizen of Morgagni and a professor at Bologna, who was at much trouble to procure old medals and portraits for the use of Salvini the sculptor, as well as of Pieroni the engraver who executed the medal bearing a likeness of Morgagni, which was presented to the company present at the unveiling of the statue. Professor Versari laid out 36,000 lire (£1440) on the statue and pedestal, which he presented to the town of Forli; his library he bequeathed to the Medico-Chirurgical Society of Bologna. Whilst the statue was in progress Professor Cesare Taruffi, who filled the chair of Pathological Anatomy at Bologna, ordered from the sculptor a copy of the bust and placed it in the upper gallery of the University of Bologna. It was evidently expected that the statue would have been unveiled in 1873, because the medal already mentioned bears that date, but in that year cholera was prevalent in Italy and in 1874 there was a failure of the harvest. The bust was unveiled on Nov. 16th, 1874.

Reviews and Notices of Books.

A Century of Vaccination. By W. S. TEBB, M.A., M.D. Cantab., D.P.H. Swan Sonnenschein and Co.

THE name of the author of this volume is well known to anti-vaccinationists and the fact that he is the son of Mr. William Tebb, one of the fathers of the anti-vaccination crusade, will ensure the book an enthusiastic welcome amongst Mr. Tebb's followers. Moreover, the methods practised throughout its pages will commend themselves to the adherents of the cause. The volume as a whole contains nothing but the old, oft-exploded fallacies of the anti-vaccinationists, augmented to a certain extent by quotations from the dissentient report of the Royal Commission on Vaccination, which has been so destructively dealt with by Dr. J. C. McVail. All the old stock-in-trade is polished up a bit and exposed for sale in a well-got-up volume to which Dr. Tebb has seen fit to give the support of his degrees and qualifications. The author has obviously been at infinite pains to collect together every word which has been uttered against vaccination while carefully disregarding every argument which may be held to support it, and he has clearly worked himself into the mental attitude of a man so enamoured with the spots on the sun that he refuses to concern himself with the sun as a whole at all. It is apparent, however, that Dr. Tebb is fully alive to the existence of all which makes for the truth, but that some strong bias, hereditary or acquired, has led him to omit nearly the whole of it and to distort what he does not omit. To quote the Registrar-General when it suits the author's purpose and to omit all reference to him when it does not is certainly one method of controversy, but it is not one which we like to see a member of the medical profession adopting. And so too with all other authorities on the subject and with the medical profession as a whole. In one breath Dr. Tebb appeals to members of the profession and in another he infers that their opinions depend upon the state of their pockets. We cannot, however, occupy space in discussing in detail the manner in which Dr. Tebb demolishes, apparently to his own satisfaction, positions created in large part by his own imagination. We will, however, in justice to the author furnish one or two examples of his methods, and as affording on the whole the least threadbare material we select his remarks on glycerinated lymph, noting, however, by the way, that almost all other parts of the volume are equally open to criticism. As is now well known it is proposed to render calf lymph free from what have been termed extraneous organisms by *storing* it in dilute glycerine until it shall have been demonstrated by bacteriological processes to be free from such organisms. According, however, to Dr. Tebb, whom by the way we can hardly believe to be ignorant of Dr. Copeman's work in this direction, the method consists "in the addition of glycerine to the lymph." In thus representing affairs Dr. Tebb betrays no little ingenuity. The addition of glycerine to lymph as a diluent or vehicle just before the lymph is used has been a common practice for years, but as far as we are aware *storage* to render lymph pure and bacteriological examination to demonstrate its purity are of very recent date. But Dr. Tebb, assuming the new method to be identical with the old, although he has apparently read Sir Richard Thorne's report upon the new methods, states: "And hence we have abundant means of testing whether glycerinated lymph is so very innocuous after all." And now having paved the way with stones of his own construction he proceeds to relate certain instances where bad results are alleged to have followed the use of lymph to which what was alleged to have been glycerine had been added. Be it noted that all this relates to the simple addition of glycerine to lymph and not to the practice which it is proposed to adopt. Away goes the author to the past and to the Isle of Rügen in the Baltic, that happy resort of all anti-vaccinationists in the time of tribulation, where some 12 years ago certain cases of *impetigo contagiosa* occurred amongst children vaccinated with lymph to which glycerine had been added. In the Transactions of the Epidemiological Society (New Series), vol. v., Dr. Tebb has discovered an account of this outbreak from the pen of the late Sir George Buchanan, and in referring to the glycerine alleged to have been used on that occasion he states that "it has been suggested by the late Sir George Buchanan that this was the cause of the untoward occurrences." We have read the paper in question—our readers can easily obtain access to it themselves—and although we cannot discover that Sir George Buchanan definitely made the suggestion referred to by Dr. Tebb we have ascertained that Sir George Buchanan stated that the lymph was mixed with thymol and that there were indications that the lymph may have been potent for harm before the glycerine was added. Dr. Tebb has omitted to mention this point and curiously enough he has, doubtless quite inadvertently, overlooked Sir George Buchanan's opinion that "in the absence of dates and other information there is little to connect the prevalent disease with the operation that pretended to be vaccination." One more instance and we must leave Dr. Tebb's book to the judgment of those who read it side by side with the papers and works from which he has so freely quoted. It has been stated that glycerine added in certain proportions to calf lymph renders the mixture in course of time sterile *quâ* extraneous organisms. But Dr. Tebb has read that glycerine added in small quantities to certain culture media enhances the growth of the tubercle bacillus sown thereon. Here, then, cries Dr. Tebb in effect, is a new danger. Shall we not all die from tubercle? He must, however, know quite well that it is not proposed to use glycerine in such small proportions as are here in question, and he knows, too, that certain doses of arsenic or of mercury are good respectively for some skin diseases and some phases of syphilis. Does he, therefore, because too large doses of either of these drugs may produce a fatal result desist from employing them altogether? Surely, too, the author is cognisant of the fact that tubercle in selected calves is of extreme rarity, that tuberculin will detect even these cases, and that, furthermore, the calf can be killed and examined before the lymph which it yielded is distributed. Why does he not then, in common justice to his readers, place these facts before them?

A Text-book of Diseases of Women. By CHARLES B. PENROSE, M.D., Ph.D. Second edition. With Illustrations. London: Rebman Publishing Co. 1898. Demy 8vo. Pp. 515. Price 20*s*.

THE fact that this book has reached a second edition in a little less than one year shows that it has supplied a want. It gives a good representation of the views held by American gynæcologists at the present day and, as might be anticipated, some of the theories advanced and the practice advocated would not be unhesitatingly accepted by all gynæcologists in this country. It is, however, always as well to see what other people are doing and saying, and for this reason as well as for others the book will well repay perusal. In the chapter upon Injuries to the Perineum there is a good clinical account of the appearance presented by the perineum when the muscles of the pelvic floor are involved in the tear. The author does not apparently recommend the flap-splitting operation for repair of the perineum, but denudation of the parts and the removal of all cicatricial tissue before suturing. Emmet's operation for laceration of the

Digitized by Google

vaginal sulci is well described with illustrations. The section upon the Position of the Uterus contains a clear account of the varying conditions of the intra-abdominal pressure and the effect they have in favouring prolapse. In considering anteflexion of the uterus we note that the author still adheres to the view that the dysmenorrhœa so often associated with this condition is due to the accumulation of blood behind the obstruction in the cervical canal—a view almost, if not entirely, given up in this country. There is a good account of trachelorrhaphy and amputation of the cervix illustrated by some very instructive figures. The curious condition known as congenital erosion and split of the cervix has a chapter specially devoted to it, giving it an importance which we hardly think it deserves. The chapter on Cancer of the Cervix is full and instructive, although we might take exception to the statement that the chief predisposing cause is a laceration of the cervix, a statement still unproved by facts. The views of the author as to the treatment of fibromyomata of the uterus may be gathered from the sentence on page 241: "The great majority of fibroid tumours demand immediate operation." As to the truth of this we fancy there still exists a great difference of opinion. He prefers hysterectomy to salpingo-oöphorectomy and considers that at the present time the danger of the two operations is almost the same if those cases only be compared in which either operation could be performed. The great importance of acute and chronic salpingitis is duly pointed out and Dr. Penrose is cautious about recommending the various conservative operations upon the appendages which have lately come into vogue. In most cases of tubal disease he considers it safest to perform a bilateral extirpation. The chapter upon Tubal Gestation, although short, is clear, and stress is laid upon the fact that operative interference is called for in almost all cases. Under Ovarian Cysts a very helpful table is given of the chief differences between oöphoritic, paroöphoritic, and parovarian cysts. The importance of gonorrhœa in causing pelvic disease is held by the author to be so great that he has devoted a special chapter to its consideration. There is a good account of the technique of gynæcological operations in general and the special details of operations upon the uterus and its appendages. These chapters will be found to be very full and instructive. The author devotes some space to pointing out the great advantage of ligaturing the vessels in the broad ligament with as little of the surrounding tissue as possible rather than *en masse*. With this all surgeons will agree and there can be little doubt that the use of mass-ligatures will be more and more given up. The book is furnished with a fair index and, as we have said already, is well worth reading by those who desire to keep abreast of the views held by one of the most distinguished of American gynæcologists.

The Essentials of Histology, Descriptive and Practical, for the use of Students. By E. A. SCHÄFER, LL.D., F.R.S., Jodrell Professor of Physiology in University College, London. Illustrated by nearly 400 Figures. Fifth edition. London: Longmans, Green and Co. 1898. Pp. 359. Price 8*s*.

THE first edition of this useful compendium of histology was published in 1885 and in the thirteen years which have elapsed since that date to the present time Professor Schäfer has found occasion to add about 100 pages of letterpress and nearly 100 woodcuts which greatly increase the value of the work. The advances which have been made in the examination of the tissues and the interpretation of the appearances presented under the microscope are sufficiently evident on every page and are fully given. The very first drawing represents *in petto* the kind of progress which has been made. It is a drawing of a cell. The earlier woodcut shows only protoplasm with vacuoles and granules distributed through its substance—a nucleus with intranuclear network and nucleolus; the recent one, drawn on a much larger scale, shows the granular protoplasm of the cell as consisting of a network of spongioplasm containing hyaloplasm in its meshes. The distribution and variable size of the vacuoles are more clearly demonstrated, a double centrosome is shown, whilst the nuclear membrane, the intranuclear network, and the nucleolus complete the picture of the cell as far as is at present known. Several of the chapters—such, for example, as those on Cell Division, on the Structure of Muscle, on the Heart, and on the Central Nervous System—have been added or are greatly expanded, whilst every section seems to have undergone careful revision. The large personal experience of Professor Schäfer in the use of the microscope adds greatly to the value of the work by enabling him to select the good and reliable work of others and serves to render it the most authoritative work on histology in the English language.

Diseases of Women. By J. C. WEBSTER, B.A., M.D., F.R.C.P. Edin. With 241 Illustrations. Edinburgh and London: Young J. Pentland. 1898. Pp. 678. Crown 8vo. Price 14*s*.

THE author of this work might well have pleaded as an excuse for its appearance the success of his book on Ectopic Pregnancy, but he has not done so and indeed no such excuse is necessary. He has well fulfilled the aim he sets before himself in the preface of regarding his subject from a scientific basis, of considering the clinical features in their widest relationships, and of recommending due caution with regard to the adoption of therapeutic measures the usefulness of which is still undetermined. The book is one of considerable interest and gives a clear exposition of the subject of which it treats. It commences with a full description of the pelvic organs, the interest of the anatomical details being considerably enhanced by the addition of notes on development and in some places on comparative anatomy. The third chapter, one of the most suggestive in the book, as might be anticipated from the special work done by the author on this subject, contains a very clear account of the pelvic floor regarded from the point of view both of dissections and of frozen sections. In a chapter upon the Nervous System in Relation to Pelvic Diseases considerable stress is laid upon the importance of regarding many cases of chronic pain from the point of view of the general physician rather than from that of the specialist, a caution which cannot be too strongly insisted upon in any text-book of gynæcology. In considering the bacteriology of the pelvic tract the *rôle* of the gonococcus and of the tubercle bacillus in the production of pelvic diseases is fully discussed, and the reason why there exists a tendency at the present day to dispense with vaginal injections in connexion with labour is explained by the results of the researches upon the bactericidal action of the vaginal secretion. The section devoted to Operative Measures in General contains a full account of the various details necessary in the treatment of a patient before and after operation, and with its assistance the young practitioner should be enabled, as far as book-teaching can help him, to recognise any of the commoner complications likely to ensue, for instance, in the after treatment of a case of abdominal section. In connexion with pelvic hæmatocele the author recognises the possibility of its occurrence apart from ectopic gestation and calls attention to Gardner's two most interesting cases of pelvic hæmatocele associated the one with adenocarcinoma of the ovary and the other with tuberculous disease of the Fallopian tube. A good account is given of

Digitized by Google

tumours of the ovaries and the chapter is illustrated by numerous outline diagrams which will be useful in enabling the student to remember the commoner tumours likely to be mistaken for ovarian cysts. The illustrations on the whole are fair, but it seems a pity, if the author thought it really necessary to insert an illustration of an ordinary trocar, that he did not choose a more modern type of instrument than the one figured on page 400. Under Inversion of the Uterus we notice that the author describes in some detail amputation of the inverted fundus, a mode of treatment which we imagine hardly anyone would adopt at the present day in preference to vaginal extirpation, surely a much better and safer treatment for an irreducible case of inversion. As might be expected in a modern text-book the operative treatment of fibro-myomata of the uterus is fully described and a considerable amount of space is given to a consideration of the various operations which can be performed. We fail, however to find any clear indications given as to what are the conditions justifying operative interference and we are left uncertain as to whether the author would agree with those who maintain that all fibroid tumours causing symptoms should be operated upon, or whether he would agree with those who still think, in spite of all that has lately been maintained to the contrary, that the great majority of fibroid tumours can be perfectly well treated without operation. In describing and criticising the various views held as to the mechanism of prolapse of the uterus Dr. Webster calls attention to the important part played by the pelvic fascia, and points out that many of the writers upon this subject have entirely neglected to take into account the support given to the pelvic floor by the fascial layer. In the chapter upon Affections of the Urethra and Bladder a good and clear account is given of the various operations employed in the treatment of genito-urinary fistulæ. As an appendix to the book the author has contributed a very suggestive and interesting account of menstruation, including a consideration of the various views held as to its nature, causation, and relationships. From biological considerations he is lead to regard the menstrual function as a highly specialised means of balancing the anabolic and katabolic factors of tissue metabolism, a function which has become established in the higher mammals by a gradual process of evolution.

The book as a whole is one which we can confidently recommend to the student and the practitioner.

LIBRARY TABLE.

Autour d'une Épidémie: Bayonne 1837-1897. (Epidemic Cerebro-Spinal Meningitis in Bayonne from 1837 to 1897). By Dr. C. DELVAILLE. Paris: A. Maloine. 1898. Pp. 38. To trace the course of an infectious disease which prevailed throughout an extensive district sixty years ago is a task of magnitude, and Dr. Delvaille of Bayonne is to be complimented on the industry with which he has consulted epidemiological treatises, obtained information from parish records and local *maires*, and collected the reminiscences of aged people at various places. At the beginning of his essay he gives clinical histories of four cases of cerebro-spinal meningitis which occurred among civilians in Bayonne in February, March, and May, 1897, two of them being fatal. During February there were also eight cases, with four deaths, and in the end of December six cases with three deaths among the soldiers of the garrison. The historical inquiry shows that there were twenty-four deaths of soldiers from the disease in Bayonne in 1837, and that its prevalence among the civilian population caused serious alarm in many parts of the adjacent department of the Landes in 1837 and 1838.

Journal of the Scottish Meteorological Society, with Tables for the Years 1895 and 1896. Edinburgh and London: William Blackwood and Sons. Pp. 248. Price 15*s*.—The current number of this journal, which is an annual publication, contains four original papers and about 170 pages of tabular matter. The observations for 1895 show that during the memorable frost in the early part of that year the temperature repeatedly fell below zero Fahrenheit at many stations in Scotland, the lowest temperature observed being −17·0° F. at Braemar, in Aberdeenshire, on Feb. 11th. "This exceedingly low temperature is further remarkable as being absolutely the lowest temperature hitherto observed in any month or anywhere in the British Islands with a properly protected thermometer." The reports made by the council to the general meetings of the society contain copious references to the value of the work done at the Ben Nevis Observatories, the expenses of which have unfortunately come to be in excess of the available funds. The observations made there from 1888 to 1896 are sufficient to fill two large quarto printed volumes.

Lectures on Asepsis in Surgery: Delivered in Arabic at the Cairo Medical School. By H. MILTON, M.R.C.S. Eng., L.S.A. Cairo: Al-Muktataf Printing Office. 1897. Pp. 113. Price 20 piastres (4s.).—One of the many benefits conferred on Egypt by the British occupation is the sound medical training provided for such native practitioners as may be willing to learn European methods. Mr. Milton's course of five lectures on asepsis, delivered in the vernacular and printed in English and Arabic arranged in parallel columns, is both a literary curiosity in consequence of its bilingual character and an excellent practical manual well adapted for students and nurses. The principal subjects treated of are as follows:—Elementary Bacteriology; Sterilization of Instruments, Dressings, Hands of Operator and his Assistants, and Patient's Skin; Application of Antiseptics to Operation Wounds; Changing of Dressings (in Cairo two days is the longest safe limit); Washing Out the Peritoneal Cavity; Drainage; Treatment of Compound Fractures. The lines of the English and Arabic printed columns are parallel to the back of the book.
